The Use of Context Data in Elective Surgery Scheduling and Planning

- *A literature review*

Marie Knutsen

Master's Thesis in Telemedicine and E-health (TLM-3902)

May 2019

In loving memory of Niklas Owen Vik.

Thank you for teaching me what truly matters.

Abstract

The aim of this thesis is to examine how the use of context data in scheduling tools can contribute to the reduction of elective surgery cancellations. A literature review, following the recommendations to systematic reviews, was conducted in order to gather information on what context data could be used to improve elective surgery scheduling, and how the use of these data could affect elective surgery cancellations. The results indicated that the context data most mentioned concerning the improvement of the elective surgery scheduling was historical data, and information on decision-making and staff experiences. The effect most reported in the articles selected for full-text review was increased efficiency and improved utilization of resources. In addition to this, many of these articles also focused on patient satisfaction. This is in alignment with national and global recommendations for future healthcare. However, more research is needed concerning the use of context data and context-awareness in hospital settings.

Acknowledgements

This thesis represents the final work of my Master's degree in Telemedicine and E-health at The Arctic University of Norway. Working with the thesis has contributed to a better understanding of the research field. The writing process has been interesting and educational and has provided a valuable insight in the field and possible future work.

I would like to thank my supervisors Terje Solvoll and Conceição Granja, both senior researcher at the Norwegian Centre for E-health Research, for all the support and guidance. Thank you for taking the time out of your day to listen to my worries and offering a helping hand when I encountered difficulties during the process. I am profoundly grateful for all the hours spent answering questions and guiding me in the right direction.

I must also thank Karianne Lind, Inge-Håvard Hunstad, Øystein Hansen and co-supervisor Rune Pedersen, at the Norwegian Centre for E-health Research, who gave me invaluable help during the process of writing this thesis.

My sincere thanks to Kaia Elisabeth Lilly, Matilde Klaussen and Martin Schmidt for taking the time to read through the work, providing me with valuable comments and advice.

Finally, I would like to express my very profound gratitude to my family for providing me with unfailing support and continuous encouragement throughout my study and during the writing of this thesis.

Marie Knutsen

1 Introduction

Operating rooms (ORs) and surgery departments are often a major source of investment and one of the greatest sources of income in hospitals, and it is estimated that ORs contribute to more than 40 % of the total revenue in hospitals [1]. This also implies that if ORs are not utilized adequately they can contribute to loss in income and become a very costly resource [2, 3]. Depending on the surgical case and what surgical need the patient has, surgeries can be divided into two main groups:

Emergency surgeries, are acute procedures, which if delayed could lead to severe impairment or death, therefore, these surgeries cannot be postponed [4].

Elective surgeries, are pre-planned surgical procedures scheduled ahead of time. These surgeries are often beneficial and/or necessary for patients but does not demand immediate attention. Examples are elective surgeries conducted as a measure to improve life quality or surgeries to treat a non-life-threatening condition. The surgeries are planned in advance, and does not require instant treatment as opposed to acute surgeries [5].

Even though elective surgeries are planned ahead of time and both patients and surgical teams are aware of the scheduled surgery, elective surgeries are often cancelled or postponed on the day of surgery, leading to lost income for the hospital and inconvenience for patients [2, 3]. Research reveals that between 10 and 40 % of elective surgeries are not conducted at the scheduled time [3, 6-8]. Many of these cancellations happen on the intended day of surgery, and several published articles state that as many as 20 % of elective surgeries are cancelled on the day of surgery in western countries [9-11]. In addition to this, it is stated that up to 50 % of these cancellations could have been avoided [3, 12, 13]. The cancellation rates of elective surgeries are especially high in the public sector [12, 14].

Surgeries are a vital part of everyday work at the hospital both to fulfil the need of the patient, and as a source of revenue. This is also why surgery cancellations are undesirable [3]. The elective surgical problem has multiple consequences: Cancellations lead to loss of income to the hospital, increase the time for patients on surgical waiting lists, lead to work redundancy and unswervingly affect the patient [2, 15]. Hospitals use a lot of resources during the planning and scheduling process of elective surgeries. This includes maintaining and booking operation rooms, making sure surgeons and other healthcare professionals are available to

operate on the given date and time, and assembling the needed surgical equipment. In addition, the patient needs to be informed, and the hospital needs to make sure the patient is able to be present on the given time and date of the surgical appointment [3, 16]. When surgeries are cancelled the staff scheduled to operate will likely be superfluous, the OR might become a unused resources, and the hospital will experience loss of income [3, 16]. In addition to this, patients will be affected due to physical and mental preparation, taking time off work, and traveling to the hospital site [16, 17].

The decision to cancel a surgery can be made by the hospital or the patient [2]. The reasons why elective surgeries are cancelled vary. Cancellations due to hospital decision can be divided into two categories: surgical planning and medical causes [18]. When the decision to cancel surgery is taken by the patient, the reasons for cancellations are mainly due to patients not wanting to undergo surgery, refusing treatment, or that the patient is a “no-show” on the agreed day or time [3, 9, 11, 19].

In order to get a better understanding of the cancellation problem in this thesis, the *University Hospital of Northern-Norway (UNN)* is used to characterize the elective surgical problem. In 2018, 1847 surgeries were cancelled at UNN the same day that the procedures were scheduled to be conducted. The cancellations in 2018 is believed to have resulted in between 5,6 to 7,8 million Norwegian kroner (NOK) lost income for the hospital, keeping in mind that these numbers only represent the cancellations on the day of surgery, and does not include cancellations one, or several days ahead of surgery [20]. 9,3 % of all surgeries are cancelled on the day of surgery, this is approximately one out of ten surgeries a day [20]. These cancellations lead to considerable cost for the hospital and affect the patient greatly. This is information that has been acknowledged for a long time, and is now getting attention from the media and the public [20].

The reasons for cancellations of elective surgeries at UNN are multifactorial. About 88 % of the elective surgery cancellations were due to hospital related reasons, the other 12 % were patient related cancellations [18].

Hospital related reasons for cancellations on the day of surgery includes several different circumstances, such as staff members being sick, acute surgery cases with higher priority, or for instance, that essential equipment or operating room facilities are not available after all [2]. Cancellations due to hospital related reasons can be divided into two groups; planning and medical causes [18]. At UNN, medical causes represent 10 % of the cancellations, while

cancellations due to inadequate planning represent 67 % of the hospital related cancellations. The remaining 11 % were other hospital related reasons [18].

As previously mentioned, most of the elective surgery cancellations that occurs at UNN, are hospital related. Studies have shown that 67 % of elective surgery cancellations at UNN are due to bad planning [18]. Surgeries cancelled because of bad planning often includes problems concerning resource utilization; meaning requiring, for instance, enough human resources, staff and department beds, unpredicted emergency surgeries, overbooking or unavailable operating theatres due to surgeries with higher duration than initially planned [2, 18]. Other reasons for cancelling elective surgeries could be efficiency problems such as unfinished pre-operative preparation [9, 19] or unavailable operating rooms due to surgery overtime [9], or it could be due to unavailability of the surgical staff [2, 6, 11, 12]. These problems all challenge the quality care in health settings.

As a measure to decrease the cancellation rates at UNN, a Lean project was conducted with the hopes of improving elective surgical patient pathways, and in this way reducing cancellations due to bad planning and cancellations concerning efficiency problems [21, 22]. These types of projects are often used in order to increase OR productivity and cut cost [21]. The Lean project was meant to provide the needed action at the needed time to avoid underutilization and avoid overbooking [2, 22]. However, a report published in 2012 revealed that Lean was not implemented as a management model [22]. The report does state that the Lean project gave some positive outcomes, but neither the method nor thinking have been implemented at the surgical level, and is poorly implemented in the clinics [22].

The main focus in this thesis will be on hospital related reasons for cancellations. This was a conscious decision due to the high percentage of hospital related reasons for cancellations at UNN [22]. In addition, patient related reasons for cancellations are often highly difficult to foresee and control, hospital related reasons for cancellations on the other hand, are more controllable and the possibility of hindering a cancellation of an elective surgery is better from a hospital perspective as opposed to patient perspective [18].

The increasing need for improved resource utilization, increased efficiency and improved quality care in the modern society of healthcare is also acknowledged on a global level by The World Health Organization (WHO), Organisation for Economic Co-operation and Development (OECD), and The World Bank [23]. Providing the needed care or treatment, for instance surgery, at the right time and avoiding resource waste is an important part of

providing the users of healthcare with the high-quality healthcare they need [23]. Therefore, it is important to have a high functioning and well-developed health information technology platform as a tool to increase the productivity in healthcare settings. Achieving proper exploitation and predictability in patient care and treatments, and having an efficient and safe use of resources, should be a priority in healthcare politics [23]. Telemedicine and electronic healthcare systems are meant to support this work.

Improving efficiency and increased quality care in healthcare can benefit the society as a whole [23]. Creating better infrastructural pathways between different information systems in healthcare is an important part of this development, and will possibly have a multitude of benefits [24]. Such benefits include reducing cost, for instance, due to cancellations, creating a more economically sustainable healthcare system. Healthcare providers can get a more structured and updated information platform, which could possibly make decision-making easier in some cases. Furthermore, patients may even receive a higher quality treatment and the risk of error could be reduced [23, 24]. In correlation to the above-mentioned aspects from WHO, OECD, and The World Bank, the Norwegian Ministry of Health and Care Services', that states that health IT is a corner stone in the improvement of healthcare quality [25]. ICT and ICT-solutions should be a focus area in order to increase patients' participation concerning their own health according to The Norwegian Ministry of Health and Care Services' Coordination Reform [26].

The use of context data in surgery scheduling could possibly contribute in solving or decreasing the problems related to surgery cancellations. *“Context is any information that can be used to characterize the situation of an entity. An entity is a person, place, or object that is considered relevant for the interaction between a user and an application, including the user and applications themselves”* [27]. Context data involves gathering information about the context in which an IT system operates. In an IT setting, context-awareness can be described as the IT systems and hardware components ability to react or use relevant information provided by the environment or the context of surgeries, and provide a response [27, 28]. In this thesis, the goal is to gather knowledge about what, and how, context data could be used as a resource when creating a elective surgery scheduling system for hospital [27].

1.1 Background

In order to solve a practical scheduling problem by mathematical means it is necessary to create a model. Information on this topic is complex and complicated, and the information on this topic originate from reference [29]. The model must capture the crucial elements of the practical problem in the sense that it should be possible to convert a solution obtained from the model into a solution of comparable quality for the practical problem. It is also important that the solutions provided for the model must be found within a moderate amount of computation time. A major problem concerning the relation between the theory and practice of scheduling, is that most models considered in the literature, up until now, are either too simple or too complex. If a system is too simple the system is not able to reflect reality. If the system is too complex it will not be quickly solvable and, therefore, not usable. The elective surgical problem could be improved by using a context-aware model [29]. Creating a model that is closer to practice by including awareness could possibly lead to a more well developed system [29]. The system should be an aware-system in the sense that it should be able to automatically sense the context data from different sensors, including calendar information, work schedule, speciality, role, etc. and use the gathered data to suggest patient appointment schedules and resource staffing that are adjusted to the hospitals reality of operations. The model would become a context-aware system by using context data to identify the surgical patterns at the specific hospital. Furthermore, the system would use the gathered data to improve the precision of the generated schedules, adjust the generated schedules in real time, and create adaptive workflows [29].

This thesis investigates the published work in research on this field, examines what context data is needed in a context-aware model, and how context data can be applied to elective surgery scheduling in hospitals, according to published studies. To the best of my knowledge, context-based data has never previously been used for patient appointment scheduling and resource staffing [29].

In order to enable a in depth understanding of the problem and theme of this thesis, some of the most important topics of this thesis will be presented hereafter.

Scheduling: Hospitals often use a so-called “block-booking system” to plan surgeries. A block-booking system is designed to assign a medical specialty to a specific place and/or time. For instance, the system “blocks out” an operating room during a specific time frame, and during this block the surgery will be carried out [29, 30]. The block-booking system

makes it possible to repeat blocks in a fixed cycle; this is conducted by combining blocks into cyclical Master Surgery Schedules (MSS) [29]. This scheduling system has both tactical and strategic advantages. *“At the strategic level of block-booking system, the number of blocks assigned to the specialties and emergencies during a MSS cycle is determined. At the tactical level, OR-days are allocated to specialties in an MSS, such that the strategic allocation is met”* [29].

As health IT evolves and the need for efficiency increases, the need to have a more complex and reliable MSS module grows. When attempting to develop a new MSS module three main challenges are important to consider according to [29]:

First, *“Enlarging the scope of the MSS: MSS approaches embedded in commercial software consider only the impact of the MSS on operating theatre and operating staff; the goal here is to enlarge the scope to down-stream resources, such as the intensive care unit ICU and the general departments required by the patients. The solution module should be flexible enough to cope with different features that appear in different hospitals that interfere with the planning activities”* [29].

Second, *“Planning with uncertainty: Surgical management processes are subject to high variability resulting in significant deviations between intended and actual performance of surgical plans. For instance, when surgeries take longer than predicted or emergency patients arrive, it often results in overtime and possible cancellation of surgeries. When planning at an aggregate level, uncertainties are usually neglected. The challenge is to anticipate the uncertainties and incorporate them during the MSS decision-making”* [29].

Third, *“Solution approaches: The problem cannot be totally described in mathematical programming terms. The volatility of information (see previous point) makes it difficult to incorporate all uncertainty in a single solid deterministic model”* [29].

The use of context data in systems can be a favourable in order to approach these challenges [29].

The Long-term Development and Conversion (LUO) – from the Norwegian name “Langsiktig Utvikling og Omstilling” project: In June 2007, The University Hospital of Northern-Norway (UNN) established a project that aimed to create an optimal utilization of the operating capacity at UNN Tromsø. The project was named “Langsiktig Utvikling og Omstilling” (LUO), in English this translates to "Long-term Development and Conversion"

[31]. This project was created as a response to the UNN Board of Directors decision concerning saving requirements for the hospital. The Board wanted to save 175 million NOK from March 2007 to the end of 2007. As a result, all departments received an unavoidable requirement for implementation of measures to achieve economic balance in line with the saving requirements [31]. In the Operations and Anaesthesiology department one of the suggested measures to reduce cost was to decrease the number of working positions at the department. This proposal was turned down by the management at the hospital because it was considered that job cuts at these departments would have unacceptable consequences for parts of the hospitals core business, the surgical business. Instead it was decided to investigate measures to optimize the utilization of the surgical capacity, which became the main focus of the LUO project [31].

After the establishment of the LUO project, the Steering Committee found it natural to focus on the workflow at the hospital to promote interaction between different disciplines and professions within the hospital. This was done in order to ensure a more comprehensive patient care pathway. The goal was to create a better and more comprehensive patient care pathway by improving the interactions between the different professional groups at the hospital that are involved in the surgery and anaesthesiologic work [31]. A part of this work is to improve the resource utilization and to create a more efficient infrastructural pathway, and design better communication tools within the hospital and the surgical department. It has been recognized that the resource utilization in the operational and anaesthesiologic department is only sub-optimal, and that there is a need for further optimization [31]. This belief is confirmed by, among others, the fact that most operation and anaesthesiologic departments experience insufficient capacity relative to the patient groups in need of treatment [31]. This recognition is also based on comparisons with corresponding hospitals that can document significantly better capacity utilization, as well as previous investigations at UNN [31].

The LUO project revealed several weaknesses, shortcomings and inadequate organization structure in the implementation of planned surgical programs. These weaknesses were among others a poor overall system for allocation of surgical capacity, a deficient preoperative planning and coordination, and poor utilization of the operating rooms during the daytime; primarily due to late start-up in the morning and long waiting time in between surgeries [31].

Digitalization of the healthcare system: Ever since the technology was introduced in the Norwegian healthcare it has been a partial part of creating a high functioning and economic

efficient healthcare system. Health technology is recognized as a tool in the process of achieving health policy goals from national authorities. Examples of this is the national strategy plan from the Ministry of Social Affairs and Health in Norway published in 1996: “*Mer helse for hver bIT*”, which translates to “*More healthcare for each bIT*” [32]. Today a new strategy plan is in use: “Nasjonal e-helsestrategi 2017-2022”, in English: “National E-health Strategy 2017-2022” [33]. This strategy plan was created by the Norwegian Directorate for E-health on behalf of the Ministry of Health and Care Services. The plan was created in order to make a detailed and strategic proposal on how E-health can contribute to the Norwegian health sector. Corresponding plans in areas of national importance will also be prioritized [33]. The plans are created as part of the process of digitalization of the healthcare system. The focus is to have a cost productive and safe healthcare system with a shared and unified infrastructure and data foundation. This will contribute in creating an integrated and process-oriented care system in Norway [32, 33].

The process of expanding the infrastructural pathways and creating a functioning process-oriented healthcare system takes time, and there have been many projects leading up to where we are today. In 1999, the Norwegian Centre for Integrated Care and Telemedicine (NST) lead an initial assessment of the possibilities of developing and implementing a system for online access to patient information called the “Elvira” project [34]. The visions of the “Elvira” project is similar to “Kjernejournalen”, in English: “National core health record”, which is in use in Norway today [35]. Other examples of projects that have impacted the development of process-oriented systems and integrated care in Norway are: Initiative 48 from National ICT [36], this initiative is part of creating standards and clinical guidelines for process- and decision support [36], and Stortingsmelding nr 9 [37], which included important information on previous goals concerning health technology, in addition to current projects and achievements, and future ambitions in Norwegian healthcare. Because of the governmental focus on integrated care systems this has also become a priority for National ICT, the Norwegian Directory of Health, and Norwegian Centre for E-health Research (NSE) [34, 35, 37].

This thesis investigates how the use of context data in scheduling systems could contribute to a high functioning and economic efficient surgery planning system that the hospitals, the patients, and the healthcare system in general, would benefit from. The benefits are believed to decrease cost by reducing the numbers of elective surgery cancellations, and to improve

efficiency by avoiding underutilization of resources [3, 16]. This is in correlation to the “National E-health Strategy 2017-2022” that encourages a further development and modernization of healthcare technology in order to increase the quality of patient care [33].

1.2 Motivation

My personal interest in telemedicine and E-health helped me find a suitable theme by contacting one of my lecturers, Terje Solvoll, during the second semester of the study. Solvoll had an ongoing research project with Conceição Granja, concerning context-aware scheduling and allocation systems [38]. The purpose of this study is among others to investigate how the use of context-based data can affect the patient pathways and workflow in hospital settings, and to integrate process support within electronic health records [38]. I found it very motivating that the thesis could be part of a larger research project that could possibly contribute to science and make a difference in how context-based data is used in healthcare. In addition, I wanted to learn more about how systems are functioning today, and how they could be changed in order to meet the increasing need for improved resource utilization, increased efficiency and enhanced quality care like WHO, OECD, and The World Bank, the Norwegian Ministry of Health and Care Services’ all acknowledge as a need in the future [23, 26]. Furthermore, the numbers provided from UNN concerning cancellations in 2018 and the amount of lost income [20], is a problem that motivates me. The results from UNN [20], makes me want to investigate how to reduce the cancellation numbers, providing the needed treatment for patients, and avoiding loss of income for the hospital.

1.3 Research questions

This thesis examines how elective surgery cancellations could be avoided and/or reduced using context data. A literature review to gather information was conducted following the recommendations to systematic reviews. The overall aim of this thesis was to acquire knowledge concerning elective surgery scheduling and planning, in correlation to context data.

Sub-questions/secondary objectives investigated were:

- What context data can be used to improve the elective surgery scheduling?
- How can context data contribute to improve elective surgery scheduling?

1.4 Master thesis structure

This thesis is structured in four chapters. Chapter 1 presents some background information, the problem of interest in this thesis, and purpose of the research. Chapter 2 contains a thorough explanation of the research methods and how material was gathered throughout the research process. Chapter 3 presents the gathered data and the obtained results. In Chapter 4, the results presented in Chapter 3 are summaries and interpreted in order to investigate and discuss the gathered data, and to examine the data in correlation to the research questions in this thesis. Limitations and future work will also be presented.

2 Materials and methods

The study presented in this thesis consist of a literature review. In the following section the methods and materials used to answer the research question, will be presented. There will be a description of the method of choice, the search strategy, and how the information to answer the research question was gathered.

2.1 Research approach – Literature review

The aims of this thesis were to investigate literature on how context data could be applied to elective surgery scheduling in hospital settings, and if the use of this data can contribute to increased efficiency and the reduction of the number of elective surgery cancellations. A literature review was selected as the method of choice, because it contributes in examining the existing knowledge on context data in scheduling, but also, explore possibilities and contradictions for the future. In addition to this, a literature search could reveal gaps in the existing knowledge concerning the use of context data in elective surgery scheduling and reducing elective surgery cancellations [39, 40].

According to Jesson et al. “*A literature review is a re-view of something that has already been written*” [39]. A literature review is created in order to investigate published work. The reasons behind those investigations varies greatly, but it could be because researchers want to investigate the published work in a specific field, or as part of a larger research project [39].

Literature reviews can be further divided into two different approaches: the traditional review and the systematic review. The *traditional literature review* is an appraisal of the information and data that has already been identified. Traditional literature reviews can provide insight in specific views of the information of interest, this could be positive in many cases, but in some scenarios the traditional literature review could contain arguments that might be considered as biased. The *systematic literature review* is a review created to gather information on a topic and identify what works and what does not work by reviewing the research already published on the topic of interest. This type of research demands a clearly specified research question and purpose of the review. In addition, a systematic literature review needs to have a precise search approach and inclusion/exclusion criteria. Because of clearer standards in method and structure, the systematic literature review is viewed as more neutral and objective compared to a traditional literature review [39]. The systematic review collect and summarize all empirical evidence that fits into a pre-specified eligibility criteria in order to answer a defined

research question [40]. The search to identify relevant information is extensive and conducted in a systematic manner using specific methods. Therefore, systematic reviews are acknowledged as representing a high quality of evidence [39-41]. Systematic methods are used in order to select and provide information that can contribute to minimize bias, draw a conclusion, and help decision making [40].

There are, however, some study limitations concerning the choice of conducting a literature review in this thesis, these limitations are stated in chapter 2.5 *Study limitations and ethical considerations*. In an attempt to minimize bias and limitations, the literature review was conducted following the recommendations to systematic reviews.

2.2 Search strategy

In order to fulfil the requirements of a literature review researchers need to follow a certain methodology strategy. This includes stating a research question, creating a plan for the literature search, and creating inclusion/exclusion criteria [39]. In the beginning of this project a research protocol was created, including research questions and requirements clarifying the inclusion/exclusion criteria. In addition to this there was a need to decide the framework, create a suitable search string, and investigate the possible databases suitable for this study [39]. The methods for reviewing articles were established before conducting the review, and the reports did not justify any deviations from the research protocol.

2.2.1 Keywords and framework

Keywords: The goal of this thesis was to create a literature review concerning the use of context data in elective surgeries. In order to gather information, and proper literature, regarding the research question, a search to find suitable keywords for the query was conducted. The keywords were tested in different combinations in databases as a strategy to investigate the articles it provided. This tactic is useful to narrow the search and identify the most current literature, but it is time-consuming and requires a lot of trial and error in order to create a suitable search string that provides the desired information. The literature retrieved from the initial searches was used in order to find suitable keywords and terms that were later used in the final query, this query and the search terms applied are depicted in *Table 1*.

Framework: The acronym PICO is short for: Population, Intervention, Comparator, and Outcome, and is a requirement for systematic reviews [40]. The PICO search strategy was used as a framework in this thesis, in order to create a high-quality search string, retrieving

the desired information to answer the research question. Keywords were applied to the given groups and combined with the Boolean Operator OR. The accumulated results of the groups were combined with the Boolean Operator AND. Comparator (C), was not applicable to this study and, therefore, not included. As a result of this work, three groups (Population, Intervention, and Outcomes), consisting of 22 terms were chosen and used as keywords in the search, these terms are depicted below.

Table 1- Keywords used in the literature search presented in a PICO framework

P (population)	<p>Surgical ward</p> <p>Surgical theatre</p> <p>Surgical department</p> <p>Operating theater</p> <p>Operating room</p> <p>Planned surgery</p> <p>Planned surgeries</p> <p>Surgical planning</p> <p>Surgical team</p> <p>"Elective Surgical Procedures"[MeSH]</p>
I (intervention)	<p>Scheduling</p> <p>Planning</p> <p>Management</p> <p>Staffing</p> <p>Appointment</p> <p>“Appointments and Schedules”[MeSH]</p> <p>“Personnel Staffing and Scheduling Information Systems”[MeSH]</p>
C (no comparison)	
O (outcome)	<p>Perspectives</p>

	Narrative
	Narratives
	Attitude
	Attitudes

In the population (P) section of the framework, the search string states that the desired information should include words concerning surgery, therefore, the section includes several different synonyms and discretionary words concerning this theme. By stating this in the population part of the framework there is no need to re-state it in other parts of the framework. There is, for instance, no need to include “surgery scheduling” or “surgical team management” in the intervention (I) part of the framework, because the PICO structure already stated that the desired theme has to do with surgery and management. The comparator (C) was not applied in this research because the articles were not required to have a comparison in order to be included in the study, and the outcome (O) section of the framework includes desirable words to describe the outcome of interest. The terms in the outcome-section were selected because the desired articles aimed for in this thesis should include experiences gathered from staff and/or users of surgical healthcare.

2.2.2 Scientific databases

In addition to deciding suitable keywords, a decision on what databases to search within was also needed. In systematic literature reviews there is a requirement of using at least two databases [39]. Several different databases were checked for adequacy on this topic to get an overview over the provided search results. The databases PubMed, Scopus and IEEE Xplore were chosen for possible extraction of data. These databases were considered in order to retrieve information from both the medical, sociological, and technical point of view. When the final search string was finished, the query was tested in the three selected databases.

After searching the databases with the finished query, IEEE Xplore was excluded. This decision was made mainly because of two reasons. First, IEEE Xplore provided a result of 34,120 items; this workload was not feasible with the given time of the thesis. It should be noted that there is a possibility that the huge number of items in this result was due to an error in the search within IEEE Xplore. However, the search was conducted with the help of an academic and research librarian, and tested in numerous ways without succeeding in

retrieving a result with a lower number of items. Second, IEEE Xplore is indexed in Scopus, meaning that the results in Scopus would include searches from IEEE Xplore [42]. This does not mean that including IEEE Xplore would not affect the search result given it is a large database, but because of the time constriction during this thesis, and the number of items provided in IEEE Xplore, the database was excluded. This left the databases PubMed and Scopus that were used for extraction of data.

2.2.2.1 Selected databases

In this section the selected databases will be presented shortly. Following this the searches within the two databases will be explained. There will also be an in-depth description of the searches within PubMed and Scopus describing the search and filters used.

PubMed: PubMed is produced by the National Library of Medicine, and the National Center for Biotechnology Information (NCBI) runs the database. PubMed provides access to MEDLINE, life science journals, and online books [43]. It is the biggest medical database, containing over 27 million references, and individuals can use it without cost [44].

The National Library of Medicine also allows you to use Medical Subject Headings (MeSH) when searching within PubMed. MeSH terms can be used in order to index articles, this can help individuals to find relevant articles because by using MeSH terms the database is not only searching that specific term, but also, other subheadings linked to the MeSH term, creating a broader search [45].

In some cases, the number of search results might be so large that it is not possible to go through all articles. In these cases, PubMed gives the user the opportunity to narrow the search by search restrictions. This could be done in several different ways, for instance, the search can be restricted by choosing to only include articles with the desired keywords in the title and/or abstract of the article. If one for instance chose to only include articles with the desired keywords in title and abstract, it implies that all articles within the search result includes one or several of the keywords in the search string. If desirable the search could be further narrowed by applying filters such as publication date filters, language filters, or restricting the search to certain types of articles, for instance, only reviews, etc. [46].

Querying PubMed: When searching in PubMed all keywords were put into a given group following the PICO structure. Due to a large amount of hits on the search terms in the first

part of the investigation, the search was restricted to title and abstract. This was decided in order to narrow down the search and obtain the most relevant articles.

In addition to regular search terms, three Medical Subject Headings (MeSH) were also used. This was done in order to, not only search the given term, but also subheadings of the term to broaden the spectrum of the results [45]. Furthermore, filters were determined to specify the findings. Filters used in PubMed were language restrictions, only English language, and full text availability. In addition to this the publication date was restricted to custom date, making it possible to restrict the search to the date when the query was finished, and the final searches started. This date was set to 2018/11/30.

Scopus: Scopus is owned by Elsevier and it is the largest abstract and citation database of peer-reviewed literature in the world. Scopus provides access to scientific journals, books and conference proceedings, and it includes multiple research topics across all scientific and technical disciplines [47].

PubMed offered the possibility to use Medical Subject Headings (MeSH) in the search. This was not possible in Scopus because: *“In Scopus MeSH terms can be searched only as Keywords, so thesaurus searching of Medline records in Scopus is limited. Terms cannot be explored, nor can subheadings be applied, and this imposes limits which make Scopus alone inadequate for high level biomedical searching”* [48]. Therefore, these search terms were searched for within keywords, title and abstract.

Just like in PubMed, the number of hits could sometimes be so large that it was not possible to go through all articles. In these cases, Scopus gives the user the opportunity to narrow the search by restricting it, but with some variation to PubMed. For instance, the search can be restricted by choosing to only include articles with the desired search terms in the title *or* abstract. It is not possible to search for desired terms in *both* title and abstract. It is, however, possible to search for the desired terms in title, abstract and keywords [49]. Scopus also allows the user to narrow the search even more by applying filters such as language filters or publication year filters [50].

Querying Scopus: When searching in Scopus all keywords were put into a given group, following the PICO structure described above. Due to a large amount of hits on the search terms in the first part of the investigation the search was restricted to title, abstract, and keywords to narrow down the search and obtain the most relevant articles. This is somewhat

different from the search in PubMed because of the additional search within the keyword section of articles.

Like explained above, MeSH terms do not have the same function in Scopus as in PubMed. Therefore, it was not searched directly for MeSH terms in Scopus, but the terms were set in punctuation marks, in this way the words would not be searched for separately, only as a sentence, and searched for within title, abstract and keywords. This is depicted in *Table 2*.

Furthermore, filters in Scopus were determined to specify the findings. PubMed and Scopus have some differences. The filter for only including articles in English language was applied. There was not an option for choosing a full-text availability filter in Scopus. As opposed to PubMed, Scopus does not allow date restriction, only years. Therefore, the year 2019 was excluded. This means that there is a one-month difference in the two databases. This inequality was not discovered in the beginning, because it was assumed that Scopus also would allow date restriction. Although the query would be more optimal if it was the same date in the searches in both databases, it was decided to keep the first date restriction in PubMed, because the work of reading through titles had already started at that point. This will be further discussed in *Chapter 4 Discussion and conclusion*.

2.2.3 The search string

The keywords were applied within PubMed and Scopus search request following the PICO structure. The terms within every group were combined with the Boolean Operator OR and the accumulated results of the groups were combined with the Boolean Operator AND. It was restricted to title and abstract, or, title, abstract and keywords, to narrow down the search and obtain the most relevant articles. As explained above the MeSH headings were not applied in the same way in PubMed and Scopus.

Table 2 - How the search was conducted within PubMed and Scopus

		Database	
ID	Keyword	PubMed	Scopus
#1	Surgical ward	[Title/Abstract]	TITLE-ABS-KEY
#2	Surgical theatre	[Title/Abstract]	TITLE-ABS-KEY
#3	Surgical department	[Title/Abstract]	TITLE-ABS-KEY

#4	Operating theater	[Title/Abstract]	TITLE-ABS-KEY
#5	Operating room	[Title/Abstract]	TITLE-ABS-KEY
#6	Planned surgery	[Title/Abstract]	TITLE-ABS-KEY
#7	Planned surgeries	[Title/Abstract]	TITLE-ABS-KEY
#8	Surgical planning	[Title/Abstract]	TITLE-ABS-KEY
#9	Surgical team	[Title/Abstract]	TITLE-ABS-KEY
#10	"Elective Surgical Procedures"	[MeSH]	TITLE-ABS-KEY
#11	#1 OR #2 OR #3 #5 OR #6 OR #7 OR #8 OR #9 OR 10		
#12	Scheduling	[Title/Abstract]	TITLE-ABS-KEY

#14	Management	[Title/Abstract]	TITLE-ABS-KEY
#15	Staffing	[Title/Abstract]	TITLE-ABS-KEY
#16	Appointment	[Title/Abstract]	TITLE-ABS-KEY
#17	"Appointments and Schedules"	[MeSH]	TITLE-ABS-KEY
#18	"Personnel Staffing and Scheduling Information Systems"	[MeSH]	TITLE-ABS-KEY
#19	#12 OR #13 OR #14 OR #15 OR #16 OR #17 OR #18		
#20	Perspectives	[Title/Abstract]	TITLE-ABS-KEY
#21	Narrative	[Title/Abstract]	TITLE-ABS-KEY
#22	Narratives	[Title/Abstract]	TITLE-ABS-KEY
#23	Attitude	[Title/Abstract]	TITLE-ABS-KEY
#24	Attitudes	[Title/Abstract]	TITLE-ABS-KEY
#25	#20 OR #21 OR #22 OR #23 OR #24		
#26	#11 AND #19 AND #25		

2.2.4 Inclusion/exclusion criteria

A list of inclusion/exclusion criteria was determined, in order to retrieve useful information that enables answering the research question, and to limit the amount of results. The inclusion/exclusion criteria list is depicted in *Table 3*.

2.2.4.1 Inclusion and exclusion criteria

Table 3 – List of inclusion criteria.

Inclusion Criteria
Research had to be published in English language
Full-text must be available.
The study had to deal with elective surgery appointment scheduling and/or cancellations of elective surgery appointments.
The study had to include at least one of the following items: <ol style="list-style-type: none">1. Mention at least one factor that can be considered as relevant when it comes to context-aware methods in surgery planning, and/or managing elective surgery cancellations.2. Mention methods that have an impact in surgical planning or impact of elective surgery cancellation.3. Include a technological aspect in the work of planning and/or avoiding cancellations of elective surgeries.4. Factors that were considered relevant to description of user pathways

In addition to the list of inclusion criteria presented in *Table 3*, some other factor should be mentioned: Because the research question deals with a rather new topic in E-health, both peer reviewed articles and grey literature, such as reports, can be included if viewed as relevant. The peer-reviewed articles are written by experts in the field, and the text is reviewed by other experts before it is published in a journal [51]. The research has been approved by experts in addition to being read and assessed during the work with this thesis to determine if it could be included to answer the research question. This is a good way to insure high quality data, and it also works as a measure to insure quality control [51]. The grey literature has not been peer reviewed but was read and assessed according to this thesis and its inclusion criteria. Grey

literature was only included if it met the inclusion criteria and was viewed as highly relevant and credible.

For this thesis it was chosen to include original studies, conference proceedings, reviews and editorials if viewed as relevant to the research question and the thesis. There is a possibility that some relevant reviews will include studies that might not have been found applicable due to the keywords and search string used for this thesis. These studies might use different terms and keywords but could still be highly relevant to investigate how context-aware methods affect surgery planning in hospitals and if using these methods can contribute to avoid pre-elective surgery cancellations.

Articles that did not meet the inclusion criteria, seemed to lack information or had no relevance were excluded. This could for instance be during the screening of titles. Titles that did not provide any information about the content of the article was excluded. An example of this was an article with the title "*A little imagination*" [52]. This article could possibly have contained valuable information, but the title did not meet the inclusion criteria and gave little information about what material the article contains, and therefore, it was excluded.

2.3 Selecting the articles

The finished search string was searched for within both databases, following this all titles were read through and screened for relevance. After reading through the titles, abstracts of relevant articles were read and screened for relevance following the inclusion/exclusion criteria. While reading the abstracts each article was moved into one of three possible groups: "include", "in-doubt", or "exclude". The articles were read in alphabetical order, and notes were made for every article explaining why it was placed in its given group. Some articles were placed in the "in-doubt" group in the screening of abstracts if it was believed that the article might contain valuable information. Therefore, a second reading was performed, where the abstracts of the articles in the "in-doubt" groups were read through once more in order to decide if the articles were relevant. The second reading was done in high focus settings where more thorough notes were taken in order to decide if the abstract gave enough information, and if the article met the inclusion/exclusion criteria. The articles left were articles selected for full-text review. These articles were read through and if they still fulfilled the inclusion criteria and had relevance to the thesis and the research question the article was included in the result of this literature review.

2.4 Data-extractions form

The data-extraction sheet was created in the beginning of the project and included in the project description of this thesis. This data-extraction sheet was designed in order to extract data from the articles selected for full-text review in an appropriate manner. Four categorized tables were created, within each table, groups were created in columns, in order to retrieve the desired data, and are explained hereafter. The first column in every group was always the reference citation in order to keep track of the origin of the data.

The first table, shown in *Table 4*, was titled “Categorization of article”. Six columns were included in this table. The first column included Reference citation; this column is the same in all four categories and will not be shown in the tables. The second column included Authors, this was in order to know who wrote the paper. The third column included Year, this was in order to know when the study was published. The fourth column included Title, this was needed to know the name of the paper and to give some insight to the theme of the article. The fifth column included Country, this was helpful to understand culture, possible economic variables considering if it was a developing country or a industrialized country. In addition, information about the country provides an opportunity to gather knowledge about health problems in the relevant country if needed. The sixth column included information on Type of hospital, for instance private or public, this was helpful in order to have an understanding of the economic aspects and founding. If the department was stated this was also noted to better understand the study of interest.

Table 4 - Categorization of article

Categorization of article				
Author	Year	Title	Country	Type of hospital (private/public etc.) & department

The second table, *Table 5*, was titled “Categorization of study”, including seven groups: Reference, Description of intervention/phenomena of interest, System in use, Phase of study, Focus, Purpose/aim/goal, and Economic variables. Column two included the description of the intervention, or the phenomena of interest, this was important information in order to

understand what the study concerned. Column three described the system in use, including the name of the system and other important information. Column four included information concerning if the article was published pre-implementation, during implementation or post-implementation. Column five included information on the focus of the article. Column six was important in order to know the purpose/aim/goal of the study. Last, in column seven, economic variables were noted if this was mentioned in the article. This was helpful to investigate if the study had investigated the economical aspect.

Table 5- Categorization of study

Categorization of study					
Description of intervention/phenomena of interest	System in use	Phase of study	Focus	Purpose/aim/goal	Economic variables

The third table, *Table 6*, was titled “Methodology”, including eight groups: Reference, Method (type of study), Data collection method, Data analysis approach, Sample size, Method for recruitment of participants, Duration of participating, and Profession(s) in focus. Column two included information on type of study and method. Column three included data collection method, this was important to understand how the data presented in the papers was collected. Column four included information on the approach concerning data analysis, this was important in order to know how the data was examined. Column five included the sample size, this is important to get an understanding over the study participants and the size of the subject pool. Column six includes information on how participants were recruited. Column seven includes information on the duration of study participation, this is important in order to know how long the study of participants lasted and to give an estimate on whether it was a long-term, medium-term or short-term study. The last column, column eight, included information on profession/professions in focus if this was stated. This was helpful in order to know if the gathered data concerned one specific profession or point of view.

Table 6 - Methodology

Methodology						
Method (type of study)	Data collection method	Data analysis approach	Sample size	Method for recruitment of participants	Duration of participating	Profession(s) in focus

In the fourth table, *Table 7*, the table was divided into two data-extractions parts gathering data concerning the *outcomes* and *results* of the study and, therefore, titled “Outcome and Results”, this table included seven columns.

In the *Outcome* section of the table, four columns were created: conclusion, response rate, limitations and ethical considerations. Column two included information on the conclusion the authors stated in the article. The third column included response rate, so if studies included a questionnaire the response rate could be documented in order to know how many answered the questionnaire. Column four included limitations in order to note if the authors addressed limitations to the study. Column five included limitations in order to note if the authors declared any ethical issues or mentioned ethical perspectives. In the *Result* section two columns were created: Data item (data collection), this was the sixth column, and Effect, which was the seventh column. Column six included the collected data in the study presented in the article, this was the knowledge retrieved from the study the authors used to draw conclusions from, and was, therefore, important. Column seven included the effect of the intervention if there was an intervention in the study, or the effect of different measures taken in the study.

Table 7 - Outcome and Results

Outcome				Results	
Conclusion stated in the article	Response rate	Limitations	Ethical considerations	Data item (data collection)	Effect

2.5 Study limitations and ethical considerations

The Cochrane Handbook for Systematic Reviews of Interventions [40] state that two researchers should review the literature, select the relevant articles and present the result [40]. This thesis is an individual paper making the approach difficult to complete in full as a systematic literature review. The abstraction of data and decision-making of which studies to include and exclude was conducted by one person; meaning that the decision on what articles to include or exclude in this thesis was not controlled by another investigator. This may lead to bias or errors, but the systematic nature of the study, the data-extractions, and the inclusion and exclusion criteria was investigated and approved by two supervisors, both before and after the search was conducted. This, alongside with following the Cochrane Handbook's guide [40] and the PICO framework [40], could make this thesis more objective than a traditional literature review.

Studies should in some cases conduct a bias-analysis in order to assess the validity of the study. A bias-analysis measure the risk that the study over- or underestimated the effect of the intervention, and in this way represent a deviation from the truth concerning the study results [40]. There was, however, no need for a bias-analysis in this thesis because the desired information in the literature review concerned the experiences with context data and context-awareness, and one cannot measure bias in experience and opinions.

3 Results

The search string identified 1810 articles from the two databases, Scopus and PubMed. The search in PubMed provided 199 articles without filters. When filters were applied 166 articles remained. The search in Scopus provided 1803 articles without filters. When filters were applied 1644 articles remained. These articles were imported to the citation manager EndNote X9, and sorted into a group set consisting of two groups, one group including articles from PubMed, the other including articles from Scopus. Following this, an automatic search for duplicates was conducted in EndNote X9, to find duplicated in the group set. Duplicates are articles that were both found in the PubMed database, and Scopus database. The automatic search for duplicates removed 123 retrieved articles. Following this, all articles with incomplete citations were removed; meaning removing articles missing information on e.g. author and/or journal name. This removed an additional 56 articles. 25 articles were removed because they stated that the reference type was serial, books or book chapters, which was viewed as not relevant for this thesis. When these search results were removed, a manual search to find duplicates that were not found in the automatic duplicate search was conducted. The manual duplicate search removed another 32 articles. The articles removed in the manual duplicate search usually had some inconsistency in the way the title was written, or it was published in two different journals and, therefore, not picked up by the automatic search within EndNote X9. A total of 236 articles were excluded due to duplicates or incomplete citations. The remaining 1574 article titles were read through and included or excluded by evaluating the information provided by the title of the article. Some articles were given the benefit of the doubt because titles are somewhat restricted in what they can contain, so if there was a doubt whether the article could be relevant it usually was included in order to avoid losing applicable articles in the screening of the titles. After title screening, 185 articles were chosen for abstract review. The abstracts of the given articles were read for compliance with inclusion/exclusion criteria described in *Table 3*. The articles with abstracts providing relevant information to meet the inclusion/exclusion criteria were chosen for full-text review. While reading the abstracts each article was moved into one of three possible groups. The first groups, the inclusion group, were articles that included information viewed as valuable. The second group, the exclusion group, were articles that did not meet the inclusion criteria. The third group, the in-doubt group, included articles that the researcher had trouble excluding because they could include valuable information, but the abstracts did not clearly meet the

inclusion criteria. The abstracts of these articles were, as mentioned in *Chapter 2.3 Selecting the articles*, read through a second time in high focus settings. Thorough notes were taken as a measure in order to decide if the abstract met the inclusion/exclusion criteria. After reading all abstracts, 30 articles were chosen for full-text review. In the full-text review 13 articles were excluded due to new information that was not presented in the title or abstract leading the article to not meet the inclusion criteria. The reasons for excluding the articles were: One of the articles had an English title and abstract, but the full-text was in Italian [53]. Three articles were not available for full-text review after all, the articles were requested to the library at the The Arctic University of Norway (UiT), but did not arrive on time [54-56]. Two articles concerned acute hospitals and trauma facilities [57, 58]. Five articles were excluded because they were considered not relevant, these articles had promising titles and abstracts, but the full-text review revealed that the article somehow did not fulfil the inclusion criteria [59-63]. These articles often lacked a technical intervention [63], missed crucial information on the result of the study [62], did not mention any changes in order to improve the situation [61], or in other ways lacked information making it unfit or unable to contribute to the thesis [59, 60]. In addition, two of the articles seemed to have potential but missed important information on method description and/or clearly stated results. These two articles seemed promising, but had a very theoretical and technical approach and did not provide the desired information for this thesis and were, therefore, not included in the study [64, 65]. After the full-text review, a selection of 17 articles containing helpful information were used to answer the research question. A short summary of the data extracted from these 17 articles are presented in *Table 8*. The full data- extraction sheet, including all the collected data, can be viewed in appendix A.

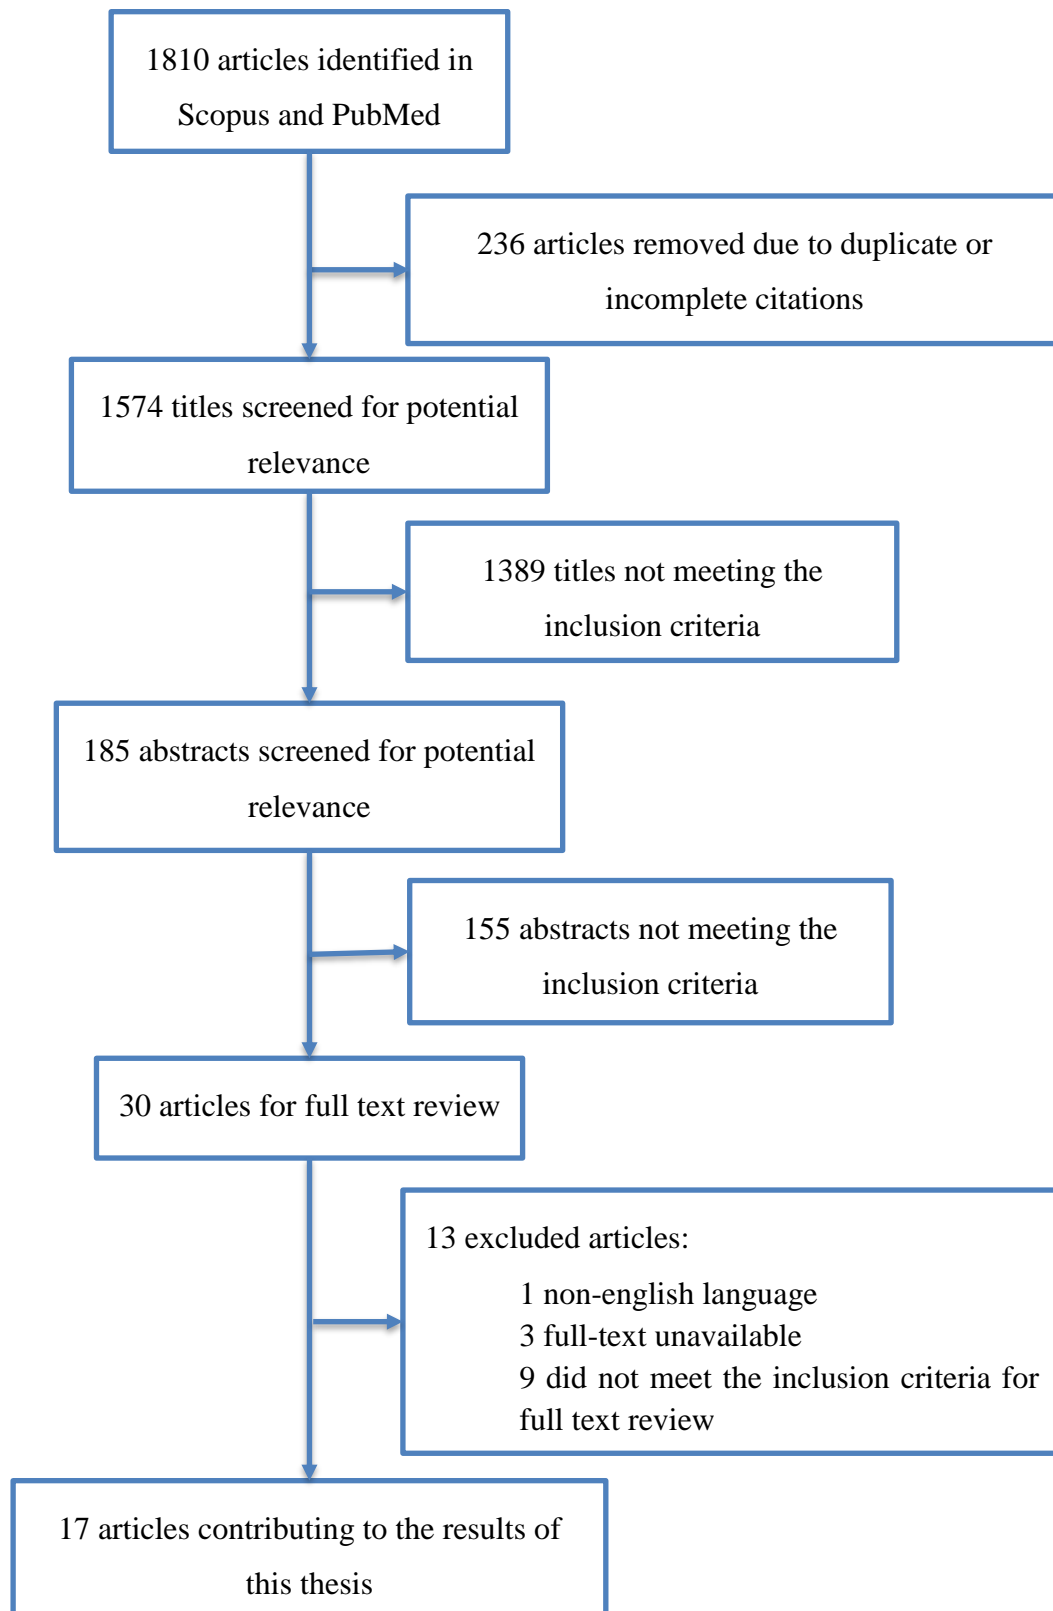

Figure 1 – Preferred Reporting for Systematic reviews and Meta-Analyses (PRISMA) flowchart of the literature search and article selection.

Table 8 - Summary of information retrieved from the 17 articles selected for full-text review. The articles are presented in alphabetical order after the title of the article.

Summary					
Ref	Author	Country	Purpose/aim/goal	Method (type of study)	Conclusion stated in the article
[66]	Gillespie, B. M. Gwinner, K. Fairweather, N. Chaboyer, W.	Australia	<i>“The aim of this observational study was to describe the strategies used to communicate decisions during surgery and the ways in which this dialog creates or compromises shared situational awareness” [66].</i>	Post observational study	<i>“Strategies used to convey decisions that enhanced shared situational awareness included the use of “self-talk”, closed-loop communications, and “overhearing” conversations that occurred at the operating table. Behaviours that compromised a team’s shared situational awareness included tunnelling and fixating on one aspect of the situation” [66].</i>

[67]	Ahmed, T. Khan, M. Khan, F. A.	Pakistan	The purpose of the paper was to investigate the reason for surgery cancellations for patients attending preoperative anaesthesia Clinic [67].	Prospective audit	The authors found that patient related reasons for cancellations were the most frequent cause for cancellations, these cancellations were viewed as uncontrollable. Anaesthetic reasons for cancellations could possibly be reduced by improving communication between anaesthesiologists and surgeons. Improving the organizational strategies might contribute to reduce cancellations related to overbooking and administrative matters [67].
[68]	Nouei, M. T. Kamyad, A. V. Sorush, A. R. Ghazalbash, S.	Iran	The purpose of this study was to develop and test a new operation room information system. The article presents the prototype “MediNav” [68].	Case study – developing a new information system (prototype)	The article states: <i>“The results reveal that integration of these systems into a complete solution is the key to not only stream up data and workflow but maximize surgical team usefulness as well. It is now possible to comprehensively collect and visualize</i>

					<i>medical information, and access a management tool with a touch-less NUI in a rather quick, practical, and harmless manner”[68].</i>
[69]	Yahia, Z. Iijima, J. Harraz, N. A. Eltawil, A. B.	Egypt	<p>The main goal of this paper is to:</p> <ol style="list-style-type: none"> 1. <i>“Evaluate the operational performance of the case mix and master surgery plans that are obtained at the higher decision levels” [69].</i> 2. <i>“Model not only the implementation part of the OR scheduling, but also to represent the ontological part” [69].</i> 	Case study – presentation of simulation model	<i>“The initial results show the simulation potential in the performance improvement of the operating room system. Furthermore, it makes understanding and exploring the system easier” [69].</i> The authors state that there is a possibility to increase the number of surgeries with around 180 more cases per year, and to reduce the overall waiting list with approximately 45 %, which among others are believed to improve patient satisfaction [69].

[70]	Westbrook, M. L. Dinn, S. E. Wilcox-Riggs, S.	USA	Summarization and presentation of the development efforts when developing a comprehensive surgical information system (SIS) [70].	Case study – presentation of the development of a new information system	The authors conclude that the comprehensive SIS developed by Madigan Army Medical Center is equal, and in some ways better than commercial products. The SIS filled a void in data collection required by the Department of Defence (DoD). The system also had less costs than buying an off-the-shelf system [70].
[71]	Fayed, A. Elkouny, A. Zoughaibi, N. Wahabi, H.	Not stated	The purpose of the paper was to investigate the rates and reasons for surgery cancellation, in addition the authors investigated the how installing new operating rooms affected the cancellation rate using statistical process control (SPC) analysis [71].	Retrospective review (detailed review of reasons for cancellations using statistical analysis)	The authors conclude that the reasons for cancelling surgeries varied greatly among the different institutes. The article states that installing extra ORs and extending the infrastructure is not the only solution to the problem of cancellations [71].

[72]	Doll, D. Kauf, P. Wieferich, K. Schiffer, R. Luedi, M. M.	Germany	<i>“To understand the impact and managerial implications of the interplay between anesthesiologists and surgeons on OR efficiency” [72].</i>	Retrospective study	<i>“A surgeon is usually predefined for scheduled surgeries (surgical list). Allocation of the right anesthesiologist to a list and to a surgeon can affect the team performance; thus, this assignment has managerial implications regarding the operating room efficiency affecting turnaround times and thus potentially overutilized time of a list at our hospital” [72].</i>
[73]	Caesar, U. Karlsson, J. Olsson, L. E. Samuelsson, K. Hansson-Olofsson, E.	Sweden	The goal of the study was <i>“to evaluate and describe the number and reasons for cancellations in elective orthopaedic surgery” [73].</i>	Retrospective observational single center study	The study concluded that the cancellation rate at the center of interest is high; 39% of all surgeries were cancelled at least once. In addition to this the study showed that many of the cancellations are avoidable. <i>“By clarifying the reasons for the cancellations, everyone involved has</i>

					<p><i>better knowledge to improve and develop better routines to reduce the number of cancelled patients. (...) The high number of cancellations in this study is a major quality problem affecting the individual patient and the actual healthcare organisation” [73].</i></p>
[74]	<p>Lehtonen, J. Torkki, P. Peltokorpi, A. Moilanen, T.</p>	Finland	<p><i>“The aim of this study is to develop a practical scheduling system that considers the advantages of both surgery categorization and newsvendor model to surgery scheduling” [74].</i></p>	Case study	<p>The study results showed a significant increase in cases per day, and the research revealed that a way to increase operating room efficiency was by <i>“planning to have one OR team to work longer” [74].</i> In addition, the authors state that in surgical services <i>“productivity and cost-efficiency can be improved by utilizing historical data in case scheduling and by increasing</i></p>

					<i>flexibility in personnel management”</i> [74].
[75]	Ahmed, K. Khan, N. Anderson, D. Watkiss, J. Challacombe, B. Khan, M. S. Dasgupta, P. Cahill, D.	England	<i>“The aim of this study was to evaluate the implementation of TPOT in urology operating theatres and identify obstacles to running an ideal operating list”</i> [75].	Report on introduction of The Productive Operating Theatre (TPOT) programme in urology operating theatres.	The authors concluded that TPOT has contributed in revealing important obstacles concerning creating functioning operating lists. In addition, TPOT improved the cumulative cost, and the efficiency in the operating theatres by reducing overrun times and increasing the number of surgeries starting on time. According to the authors patients’ satisfaction also increased due to a more efficient communication [75].

[76]	Xiang, W.	Not stated	The purpose of this study was to investigate how a meta-heuristic approach integrating Pareto sets and Ant Colony Optimization (ACO) could solve problems in optimization of multi-objective OR scheduling [76].	Computational study	<i>“It can be concluded that the algorithm can solve the multiple objective surgery scheduling problem effectively, while at the same time provide a shortening makespan and a relative balanced resource allocations” [76].</i>
[77]	Zhu, S. Fan, W. Yang, S. Pei, J. Pardalos, P. M.	Not stated	The overall aim of this paper was to provide a comprehensive classification on operating room planning and scheduling problems. The authors conducted a literature review, and reviewed the literature <i>“from the perspectives of decision level, scheduling strategy, patient characteristics, problem setting, uncertainty, mathematical models, and solutions and methods” [77].</i>	Literature review	The literature review concludes that <i>“studies reviewed in this paper clearly indicate that different decisions in different levels have a significant effect on the performance of the surgical center” [77].</i> The authors underline that most of <i>“most of the research is directed towards the scheduling problem within everyday horizon, which is very close to the actual situation” [77].</i> The

					literature review states that the articles included in the study showed that none of the theoretical work published seems to have profound effect in real-life practise or the management of ORs [77].
[30]	Addis, B. Carello, G. Grosso, A. Tànfani, E.	Not stated	Investigating how to select patients from a waiting list of elective patients and how the use of a block scheduling strategy using a rolling horizon approach could contribute to minimize the overall waiting time and the tardiness of patients [30].	Case study	The authors used a block scheduling strategy in order to solve the advance scheduling and rescheduling problem (ASRP). The article concludes that the computational results are promising. According to the authors the solution provides a better resource utilization and reduce the number of cancelled surgeries [30].

[78]	Liu, H. Zhang, T. Luo, S. Xu, D.	China	The purpose of this study: “(...) <i>solving a surgery scheduling problem with multiple ORs and multiple surgeons to minimize cost and improve utilization of operating theatre</i> ” [78].	Case study	The authors concluded that the model and methods used provided good solutions in diverse sample sizes. In addition, they state that: “ <i>Real-life constraints and duration uncertainty were considered in the study, and the model was also very applicable in practice. Average overtime of each OR was reducing and tending to be stable with the number of surgeons increasing, which is a discipline for OR management</i> ” [78].
[79]	Kumar, R. Gandhi, R.	Not stated	The aim was: “ <i>To investigate and evaluate the reasons for cancellations of operations on day of surgeries</i> ” [79].	Audit of reasons for cancellations.	The authors wanted to investigate why surgeries were cancelled on the day of surgery, and if the cancellations could have been avoided. They conclude that most causes of cancellations of operations are avoidable [79].

[80]	Pang, B. Xie, X. Song, Y. Luo, L.	China	According to the authors the purpose is to: “(...) develop an optimization model to address inefficient scheduling. The goal is that this will contribute in minimizing the costs from the perspectives of both healthcare providers and patients” [80].	Case study	“The case study revealed that the total cost can be reduced by approximately 27 %. Investigation of the value of stochastic solution (VSS) revealed the necessity of considering a stochastic programming formulation. The authors state that the developed solutions provided by the models are better than ones obtained from the current practice at the hospital” [80].
[81]	Damani, Z. Conner-Spady, B. Nash, T. Stelfox, H. T. Noseworthy, T. W. Marshall, D. A.	Not stated	The goal of the review was: “(1) summarise existing research on the scope, use and Implementation of SEMs for elective surgical services; (2) to report on the evidence about the influence of SEMs on timeliness and access;	Systematic literature review	“The review demonstrates a potential ability for SEMs to improve timeliness and patient-centredness of elective services; however, the small number of low-quality studies available makes it challenging to draw firm conclusions about the effectiveness of SEMs in

			<p><i>and (3) patient-centredness (patient and provider acceptability) of SEMs.” [81].</i></p>		<p><i>improving timeliness of access to elective procedures. Our findings show a consistently positive impact by SEMs on the access-related variables. While promising, they also prompt the need for ongoing study in critical areas, but with higher quality designs, more comprehensive scope and greater methodological rigour” [81].</i></p> <p>The majority of the studies included in this review had a weak observational design according to the authors [81].</p>

4 Discussion and conclusion

The articles included in this thesis can be categorized in three groups, depending on the content. The *first group* included articles containing reports concerning information on a system or, in other ways included information and/or data concerning context-aware systems, to a total of nine articles [30, 66, 68-70, 74, 75, 77, 81]. The *second group* comprises four articles that mainly investigated reasons for cancellations, but included some kind of information concerning how these cancellations could have been avoided [67, 71, 73, 79]. This information was viewed as valuable to this thesis considering creating context-aware programs and solutions and were, therefore, included in the study. The *third group* contained the articles that presented a mathematical approach to the problem. These studies viewed how the scheduling problem could be solved using different programming models as a suggested solution [72, 76, 78, 80]. This was also the case for the two of the articles excluded from the full-text review, that did seem promising, but had a very theoretical and technical approach and did not provide the desired information for this thesis and were, therefore, not included in the study [64, 65]. Hereafter, the three groups will be introduced and the information and findings within each articles in the given group will be presented and discussed in relation to the research question.

4.1 First group

The Madigan Army Medical Center developed their own comprehensive Surgical Information System (SIS) [70]. The system included four important aspects that were viewed as very valuable in the process. The first aspect mentioned was, that the system was created with the involvement of hospital staff and the end-users that wanted the system to succeed. The second aspect mentioned was that organizational staff and “command staff” were included in the development. The third aspect emphasizes that the developers had continuous meetings with end-users, creating the system with user classifications, so that surgeons, nurses and other surgical staff had their personalized display providing the needed information for the different roles. Lastly, the fourth aspect in the development process describes how when the system was launched as a small pilot, during which problems and errors were fixed before gradually expanding the system to the hospital [70]. These aspects contributed to the system functionality, and the authors stated that all surgical services used the SIS after implementation. The time spent on surgical scheduling was drastically reduced, in other

words, the efficiency increased. Nevertheless, a problem with the system was that the staff did not receive enough training in using the system and, therefore, many staff members continued using the previous system [70]. According to this, article the SIS implementation was a success, and it contributed to increase the efficiency at the Center. However, the authors fail to mention how they plan to train the staff in the future in order to get the system to be used at all levels. This paper is more than 20 years old (1996), and it is likely that the system might be outdated, or has drastically changed since the article was published [70].

Another study presenting development of a new system, suggests creating a comprehensive operating room information system (ORIS) [68]. The ORIS presented in the article is a prototype called “MediNav”, that was deployed in 2013 [68]. The purpose of creating a comprehensive ORIS was to create a system that could maximize workflow, and gather medical information in a safe, fast and practical manner, which is similar to the wished of development aims of the SIS in 1996, [68, 70], and can be linked to context awareness. The article, [68], addresses how it is important to plan the different surgical stages in the surgical pathway, being able to access important data and vital information quickly, but avoiding contamination; meaning transferring contaminated substances between the sterile and non-sterile zones. In addition, there might be a need to document surgical steps, for instance, by using video or audio recordings. The authors state that using Kinect sensors (motion sensing input devices), and radio frequency identification devices (RFID) in the comprehensive ORIS would be the key to offer a complete solution to comprehensively collect and visualize medical information [68]. The authors concluded that using touch-less natural user interface (NUI) could possibly contribute to the management tool, in addition to collect and visualize medical information [68]. The article states that at the time of publishing the article, the system has not been integrated. The authors also note that there is a need for further testing and comparison of system to against solutions, such as, other human-machine interfaces in order to evaluate what solution would be optimal. This is in accordance to the articles that will be presented in group three [72, 76, 78, 80], but these articles has a very mathematical approach as opposed to [68]. In [68] the authors are using context awareness when collecting data from interviews and watching and listening to the users, without referring to it as context aware data collection.

Two urology operating theatres in London introduced a programme called The Productive Operating Theatre (TPOT) [75]. The programme was developed by the NHS Institute for

Innovation and Improvement with the hopes of improving the surgery outcomes and enhance patient safety and satisfaction. The aims of this article are aligned with the two abovementioned articles [68, 70]. After the introduction of the TPOT programme the overrun times were reduced and the number of surgeries starting on time was increased. These results are believed to be consequence of the introduction of a briefing and debriefing system. The briefing system lead to staff members addressing potential issues ahead of time, and lead to a better structured operating plan leading to increased efficiency. The authors concluded that TPOT has contributed in revealing important obstacles concerning creating functioning surgery lists. In addition, TPOT improved the cumulative cost, and the efficiency in the operating theatres by reducing overrun times and increasing the number of surgeries starting on time. According to the authors patients' satisfaction also increased due to a more efficient communication [75]. It is also worth mentioning that by avoiding overrun times, one could also possibly avoid cancellations because the scheduling and OR block times are correct, leading to surgeries finishing within the planned timeframe and, therefore, avoiding cancellations due to unavailable ORs. The results presented in [75] are of great importance because they are in alignment with the needs stated in the introduction section of this thesis by WHO, OECD, The World Bank and the Norwegian Ministry of Health and Care Services' [23, 25], concerning the need for improved utilization, increased efficiency and improved quality care in the modern society of healthcare.

Another article presenting results that could improve utilization, increase efficiency and improve quality care is [69]. Here, the authors attempt to create a simulation model with focus on the essence of the system in use at the hospital of interest. A simulation model was developed using Design and Engineering Methodology for Organization (DEMO)-based simulations, and the goal was to create a more holistic view of the enterprise [69]. According to the article *"The initial results show the simulation potential in the performance improvement of the operating room system. Furthermore, it makes understanding and exploring the system easier"* [69]. The authors state that there is a possibility to increase the number of surgeries with around 180 more cases per year, and to reduce the overall waiting list with approximately 45 %, which among others are believed to improve patient satisfaction [69]. In difference to the other studies in this group, the researchers are approaching the problem by going from a detailed view to a holistic view of the information needed in surgical cases.

Another way of creating a better scheduling system, is the use of single-entry models (SEMs). In 2016 the first systematic review on SEMs for adult elective surgeries was published [81]. SEMs are suggested as a solution to decrease waiting lists and increase patient flow using a single point-of-entry, and a first-come first-serve approach. The results from the review revealed SEMs could decrease time on waiting lists and increase patient satisfaction. However, there were only a small number of studies available and these studies often had low-quality, such as case studies. Because of these findings the authors were reluctant to draw any firm conclusions about whether the SEMs do improve timeliness of access to elective surgery procedures or not. The authors do, however, stress that SEMs are promising, but there is a need for more in-dept high quality studies on the matter [81]. The first-come first-serve approach should be mentioned as a potential problem, because it is not clearly stated how many cases assessed urgency and priority. If this is not taken into consideration the model will most likely have huge problems in practice. It is, however, worth mentioning that the results from this article is in alignment with the literature review conducted in this thesis. Most of the articles used in this review are small case studies, and the quality of the studies vary, revealing that there is a gap in knowledge. Another model [30], focuses on how to reduce the overall waiting time and the avoidance of tardiness by using a rolling horizon approach. The purpose of the study was to investigate how to select patients from a waiting list of elective patients and how the use of a block scheduling strategy, that included a rolling horizon approach could contribute to minimize the overall waiting time and the tardiness of patients [30]. As opposed to several of the articles mentioned in the literature review [81], this study did provide priority to urgency cases [30]. The authors used a block scheduling strategy in order to solve the advance scheduling and rescheduling problem (ASRP). The article concludes that the computational results are promising, and according to the authors the solution provides a better resource utilization, and reduce the number cancelled surgeries[30]. It should be mentioned that the authors state that future work should involve combining surgery scheduling and bed management. The reason why this is suggested as future work is because bed availability is a significant resource that needs to be functioning in order to avoid problems in scheduling and surgery planning, and execution [30]. This information is important to keep in mind because it could be linked to the context data needed in order to have highly functioning scheduling system.

Gillespie et al. [66], focused on situational awareness and how important communication is to avoid misunderstandings and create a safe surgical environment [66]. This article mostly

focused on the communicational aspect in order to create situational awareness without clearly stating if communicational tools such as pagers, smartphones or tablets, were considered. Being able to communicate with staff members that are not in the same room but involved in the surgical process could also contribute to increased situational awareness. The authors state that by improving communicational strategies, one can improve the situational awareness within the teams, leading to a better overview, which could lead to discovering possible obstacles ahead of time and avoiding unnecessary cancellations [66].

A Finnish study published in 2013 aimed to *“develop a practical scheduling system that considers the advantages of both surgery categorization and newsvendor model to surgery scheduling”* [74]. The authors state that many of the former studies focus on mathematical modelling, this is often hard to apply in real-life environment, therefore, the researchers wanted to investigate the problem from a practical view [74]. This will be discussed later on in this thesis. The researchers applied the newsvendor model in the OR environment, including planning and scheduling. The study results showed a significant increase in cases per day, and the research revealed that a way to increase operating room efficiency was by *“planning to have one OR team to work longer”* [74]. However, this suggestion was, not described further, and it could be argued that this is not a solution but rather *“planning to be delayed”*, therefore, one could claim that instead of planning to work longer one needs to investigate if the timeframe is too narrow, causing delays. In addition, the authors state that in surgical services *“productivity and cost-efficiency can be improved by utilizing historical data in case scheduling and by increasing flexibility in personnel management.”* [74]. Limitations mentioned by the researches was, among others, that the study was conducted in a very specific setting and, therefore, the applicability to other disciplines and situations cannot be confirmed [74]. Another important point the authors make is that scheduling of surgeries are often complicated and staff working with scheduling on an everyday basis often acquire important information and experience concerning how planning and scheduling should be conducted [74], and, therefore, these experiences are important knowledge to obtain in order to create a high-functioning scheduling system.

Zhu et al. [77] published a comprehensive survey concerning problems related to operating room planning and scheduling. The review attained 315 articles, and concludes that the studies *“clearly indicate that different decisions in different levels have a significant effect on the performance of the surgical center”* [77]. In addition to this the authors underline that

“most of the research is directed towards the scheduling problem within everyday horizon, which is very close to the actual situation” [77]. It is usually beneficial to plan ahead of time, using long-term scheduling, in order to have work schedules for the surgical teams, and because the patients need time to prepare, and often needs to take time off from their own work. Therefore, a everyday horizon could be viewed as a disadvantage for both hospital staff and patients. One should note that according to the authors the review attained 315 articles, but it is not clearly stated if these were all included in the final result. The literature review states that the articles included in the study showed that none of the theoretical work published seems to have profound effect in real-life practise, or the management of ORs, implying that there is still a lot of work to implement high-functional systems in practice [77]. This is consistent with this thesis and what the results from the literature review portrayed.

4.2 Second group

A study concerning surgery cancellations on the day of the intended surgery revealed that most of the cancellations at the hospital were avoidable [79]. Causes of cancellations varied but the most common causes were lack of availability of surgical time, hence, bad planning (63 %), and no-shows (19 %) [79]. These numbers are similar to the numbers from UNN [18], revealing that the surgical planning has a need for improvement in order to decrease the number of cancellations on the day of surgery. The study [79] suggest, among other things, making OR lists judiciously with better pre-surgical planning in order to achieve the best utilization of ORs [79]. Fayed et al.[71], also investigated cancellations on the day of intended surgery. The patient related reasons for cancellations were, however, higher, representing 27 % of the cancellations [71], compared to 19 % [79] and 12 % [18]. In this study [71], patient related reasons for cancellations represented the leading cause for cancellations. One possible explanation to this could be that the study only divided the cancellations in three categories: patient related factors, facility related factors, and preoperative preparation causes [71]. The authors noted that cancellations due to respiratory infections and febrile illnesses were more frequent during the wintertime, and that these reasons for cancellations were lower during the months May through July [71]. This could mean that the number of surgeries cancelled due to infections or fever will be lower during the summertime, however, this cannot be proven based on just one study, but is valuable knowledge as part of context awareness and understanding reasons for surgical cancellations. Some elective surgery patients attend a preoperative anaesthesia clinic before surgery [67].

According to [67], 58 % of the cancellations where patients attend a preoperative anaesthesia clinic were patient related [67]. This number is significantly higher compared to the three articles mentioned in this section [18, 71, 79]. The study was published as a prospective audit and the numbers presented only represents 55 cancellations within a two-month period. This could explain the high number of patient related reasons for cancellations. In addition the study was conducted in Pakistan, and patients have to finance the surgery themselves leading patients to investigate offers at other hospitals [67]. The article do, however, mention that over-booking and bad planning also was a problem representing 5,45 % of the cancellations, and suggest that a solution to this would be improving the scheduling system [67].

Article [73] concerned cancellations of orthopaedic surgeries, and the cancellation numbers due to acute cases were high. The number of cancellations due to acute cases with higher priority could be explained when considering that this study concerned elective orthopaedic surgeries. Orthopaedic surgeries often include trauma, so patients with higher priority, for instance, due to accidents, would be prioritized a head of an elective surgery. Therefore, it was suggested to have two waiting lists, one list for acute patients, and one for elective surgeries, in order to reduce cancellations [73].

In both [71, 73], the authors mentioned that providing the patient with a call or text message as a reminder of the surgical appointment ahead of time could reduce the number of no-shows and cancellation last-minute. Also, several of the articles included information on how improving communication between doctors, nurses and patients can be used as a way of preventing problems and avoiding surgical cancellations [67, 73, 79]. In other words the articles state that patient related causes for cancellations are hard to avoid, article [79] even classify it as “nonavoidable”. However, several articles do suggest increasing communication with patients, providing information of sending reminders as a way to avoid patient related cancellations [67, 73, 79]. This thesis focuses on the hospital related reasons for cancellations, and, therefore, patient related reasons for cancellations has not been the main focus. Patient related reasons for cancellations represented 12 % of elective surgery cancellations at UNN [18]. It could, therefore, be a suggestion to implement text reminders to patients in a context-aware scheduling system, as a measure to reduce the patient related reasons for cancellations.

4.3 Third group

In 2018, an article concerning a stochastic integer programming model developed by researchers at a West China Hospital, was published [80]. In the article the authors present a

case study where they integrated a stochastic programming model at two departments, with the hopes of reducing cost for the hospital and provide better care for the patients. The article presents three decision-making problems that affect cancellation rates at the hospital [80]. First, the problems concerning patient admission. This is among other problems concerning capacity, admission and assigning surgeons to patients. Second, the problems concerning block scheduling. This problem concerns how to make choices when assigning time blocks to departments and recipients of surgery. Third, the problems concerning surgery sequencing. This problem concerns the sequencing of the surgery within the block time [80]. The case study had promising results and was viewed as a better solution compared to the current system in use at the hospital. According to the researchers, and reduced the costs by roughly 27 % [80]. However, the study also had several limitations that are mentioned and should be changed in the future. This was among other that the system was not a dynamic scheduling system, and that the research did not include emergency surgeries, which is highly necessary. The authors did address this and stated that emergency surgeries would have to be implemented in the model in the future [80].

An article published in 2017 [76], investigate how a meta-heuristic approach integrating Pareto sets and Ant Colony Optimization (ACO) could solve problems in optimization of multi-objective OR scheduling [76]. In the article the evaluation of the OR scheduling system are controlled by performance criteria such as *“waiting time, throughput, utilization, leveling, makespan, patient deferrals, cost measures and preferences, etc.”* [76]. The author divided these performance criteria into different categories. These categories were: *“patient-related measures, staff-related measures, and OR management-related measures”* [76]. The algorithm created was tested in two different test settings and the article concludes that *“that the algorithm can solve the multiple objective surgery scheduling problem effectively, while at the same time provide a shortening makespan and a relative balanced resource allocations”* [76]. However, the article states in the very end of the “Conclusion and ongoing work” section that the algorithm needs to be improved in order to solve the scheduling problems with “more realistic constraints” in order to function in an real-life surgical setting [76], meaning that as of now the system would not be a successfully implemented in hospital settings. Other articles investigated how team setups could improve efficiency using mathematic and algorithmic decisions [72]. The results showed that stable surgical teams increased operating room efficiency which improved the turnaround times and, in this manner, contributing to avoiding operating room delays [72]. One could argue that surgical

teams usually will vary due to different circumstances making it difficult to always have stable surgical teams, this includes turn-around schemes at the hospital and the hiring of additional staff.

Chinese researchers developed a stochastic model as a tool for operating room scheduling and surgeon assignment [78]. The authors used what they describe as “a two-step mixed integer programming model”. A sample average approximation method was used in order to solve the model [78]. The programming model was a two-step model: The aim for the first step was to lower the opening costs and overtime cost for the ORs. The aim for the second step was to reduce overtime in the ORs by increasing utilization. The study results displayed that the model and method provided a satisfying solution in different sample sizes. The average of overtime in the ORs was reduced and the availability of surgeons who could perform the surgery on the given day increased [78]. There are some uncertainties concerning this article, for instance, the inclusion of real-life constraints included in the model is not clearly stated, but it is noted that “more real-life constraints” are needed in the future. Additionally, the article states that emergency cases and surgery cancellations need to be introduced in the modelling process [78], meaning that these factors have not been considered in the model as of now. The article could be criticised for not clarifying these statements.

All of the above-mentioned articles included in group three presented a mathematical approach, only considering how programming models could change the planning and/or scheduling system at the hospital [72, 76, 78, 80]. Like the article by Lehtonen et. al. [74] stated in their article, included in group one, the problem with this is that this approach, is that it often fails in an actual hospital setting [74]. This can also be seen in the article concerning development of a comprehensive surgical information system (SIS) [70], where the authors stated that the use of the application encountered major difficulties in an actual hospital setting [70]. It is also worth noticing that none of the programming models had actually been implemented in a hospital setting and did require changes according to the articles’ future work section [64, 65, 76, 78, 80]. The changes included improving efficiency [64], considering dynamic scheduling systems [80], and implementing more real-life constraints, such as nurse and surgeons preference in medical teams [76, 78]. This supports the statement from Lehtonen et al. [74] concerning that studies only focusing on mathematical modelling, are often proved hard to apply in real-life environment, therefore, the problem might be more approachable from a practical view, or in a combination, in order to succeed [74].

The articles in all three groups have common traits concerning the content of the desired outcome of the studies. Therefore, the groups can be summarized as articles that in some way investigate elective surgery scheduling. The articles often aimed to investigate how to improve efficiency, enhance patient satisfaction, improve patient safety, or decrease cost/increase income [30, 66-81]. This is in alignment with the needs stated by WHO, OECD, The World Bank and the Norwegian Ministry of Health and Care Services' [23, 25] and is, therefore, a natural focus area because research on these topics could possibly get funding from, for instance, health departments in the country of interest.

The articles included in this thesis have been categorized and presented according to three different groups, depending on the content of the articles. It could, however, be worth noticing that articles excluded from the full-text review had similarities, but this concerned lack of content. For example, several articles focused on increasing resources without focusing on optimizing the systems in use. Meaning that the hospital increased the capacity of ORs or increased operating teams and resources without considering if there should have been other changes, like optimization of the scheduling system or the planning of the surgeries or surgical teams [61, 62]. For instance, Lloyd [62], suggested to have a multi-skilled staff team available to reduce the number of cancellations in standalone surgeries at hospitals, but does not mention planning and scheduling strategies in order to cooperate this team and how to avoid having superfluous staff members and redundancy in practise, therefore, risking economic loss [62]. Another example of increasing capacity without optimizing the systems used is a study at a 600-bed university hospital with ten operating rooms [61]. Here two additional operating rooms were built with the hope of reducing cancellation rates on day of surgery. The hospital did, however, not hire more staff members, nor does the article mention that any planning features or technological aspects were changes or optimized. The article concluded that the cancellation rates actually increased due to the instalment of an additional two operating rooms, and that the most common reason for cancellations after the installations of two new ORs were departmental issues [61]. This could possibly have been avoided if the hospital in addition to the new ORs also optimized the planning and scheduling systems.

The author of this thesis acknowledges that the root causes of suboptimal resource utilization are multifactorial and include all phases in patient-flow from: referenced to surgery, pre-elective surgery planning, hospitalization of patient, conducting surgery, and post-surgery. In

this work the area of focus is the technological aspect and investigating workflow and context-awareness concerning elective surgeries.

4.4 Research questions

In this section, the most relevant information gathered during the literature review, and its discussion, will be summarized and presented in correlation to the research questions in *Table 9*.

The first column in *Table 9*, identifies the group in which the article was classified, and the citation number of the article. The second column presents the most relevant data and information gathered from the retrieved articles. The third column includes information from the articles that contributes to answering the research question concerning *what* context data can be used to improve the elective surgery scheduling. The fourth column denotes the information gathered that contributes to answering the research question concerning *how* context data can contribute to improve elective surgery scheduling, including the effects it provided or hoped to achieve.

From the information in *Table 9*, it is concluded that the use of context data in scheduling tools positively affects the number of elective surgery cancellations, by reducing cancellations. The context data most mentioned concerning *what* data could be used to improve elective surgery scheduling was historical data and information on decision-making and staff experiences. The effect most articles reported, concerning *how* context data could improve elective surgery scheduling, was increased efficiency and improved utilization of resources. In addition to this, many articles also focused on patient satisfaction. This is in alignment with national and global recommendations for future healthcare [23, 25].

Table 9 - Data gathering in correlation to the research question

Group & Ref.	Data (information from the retrieved articles)	What (is needed)	How (the effects - what is the improvements mentioned/hoped for in the articles)
1 [70]	<ul style="list-style-type: none"> - Surgeons, nurses and other surgical staff had their personalized display providing the needed information for the different roles - Context-awareness 	<ul style="list-style-type: none"> - Information on how the users use the system and what information they need in surgical context 	<ul style="list-style-type: none"> - Increased efficiency (The time spent on surgical scheduling was drastically reduced) - Right information, to the right person, in the right moment
1 [68]	<ul style="list-style-type: none"> - Addresses how it is important to plan the different surgical stages in the surgical pathway - The importance of accessing important data and vital information quickly, but avoiding contamination - Physical contamination – context awareness is needed for location of the needed information 	<ul style="list-style-type: none"> - For example: they collect interviews and watching and listening to the users while they work and also questionnaires for usability satisfaction - They are using context-awareness without referring to it 	<ul style="list-style-type: none"> - Using Kinect sensors (motion sensing input devices), and radio frequency identification devices (RFID) in the comprehensive ORIS would be the key to offer a complete solution to comprehensively collect and visualize medical information - Using touch-less natural user interface (NUI) could possibly contribute to the management

	<ul style="list-style-type: none"> - Creating historical data that we can use to know what the task implies in terms of medical equipment - Tracking people by RIFD (location and context awareness) 		<p>tool, in addition to collect and visualize medical information</p>
<p>1 [75]</p>	<ul style="list-style-type: none"> - The context data used here: improved block times for OR scheduling 	<ul style="list-style-type: none"> - Introduction of a briefing and debriefing system - Data relevant for the system 	<ul style="list-style-type: none"> - Leading to staff members addressing potential issues ahead of time, and leading to a better structured operating plan leading to increased efficiency - The overrun times were reduced and the number of surgeries starting on time was increased - TPOT has contributed in revealing important obstacles concerning creating functioning surgery lists - TPOT improved the cumulative cost, and the efficiency in the operating theatres by reducing

			<p>overrun times and increasing the number of surgeries starting on time</p> <ul style="list-style-type: none"> - Patients' satisfaction also increased
1 [69]	<ul style="list-style-type: none"> - In difference to the other studies in this group, the researchers are approaching the problem by going from a detailed view to a holistic view of the information needed in surgical cases - Approaching the problem with standardized data to create more efficient scheduling systems 	<ul style="list-style-type: none"> - Using Design and Engineering Methodology for Organization (DEMO)-based simulations. Focusing on the essence of the system used at the hospital 	<ul style="list-style-type: none"> - Theoretical paper, the authors state that there is a possibility to increase the number of surgeries with around 180 more cases per year, and to reduce the overall waiting list with approximately 45 %, which among others are believed to improve patient satisfaction

<p>1 [77]</p>	<ul style="list-style-type: none"> - The problem is on the operational and strategic levels – patient pathway data or patient related data that could change the pathway 	<ul style="list-style-type: none"> - Literature review - Use the lack of context-awareness to make the operating rooms more general (They are lowering the speciality level in order to increase efficiency in each operation room) 	<ul style="list-style-type: none"> - None of the theoretical work published seems to have profound effect in real-life practise, or the management of ORs - Planning on a strategic, tactical and operational level
<p>2 [79]</p>	<ul style="list-style-type: none"> - Gathering data regarding surgical cancellation on the day of surgery - Common causes were lack of availability of surgical time, hence, bad planning (63 %), and no-shows (19 %) 	<ul style="list-style-type: none"> - There is a need for increased knowledge about the systems in use at the hospital, and the patient flow - Better pre-surgical planning means more information on the patient, pathway and 	<ul style="list-style-type: none"> - Making OR lists judiciously with better pre-surgical planning in order to achieve the best utilization of ORs - Suggests call/text reminders to patients to avoid no-shows

		<p>resources selected to be used by the patient prior to surgery. For example, be aware of the patient health status, possible vacations of resources (keep track if the resources remain available), further examinations required (changes in the pathway)</p>	
<p>2 [71]</p>	<ul style="list-style-type: none"> - Gathering data regarding surgical cancellation on the day of surgery. E.g. statistical data and seasonal changes do affect the cancellation rate, with less febrile illnesses during summertime vs. winter 	<ul style="list-style-type: none"> - Gathering context data by investigating why cancellations of surgery occurred to provide a possible solution - Again, be aware of the patient health status (other pathologies that might have appeared that hinder surgery) 	<ul style="list-style-type: none"> - The article suggests installing additional operating rooms - Suggests call/text reminders to patients to avoid no-shows

<p>2 [67]</p>	<ul style="list-style-type: none"> - Gathering data concerning surgery cancellations of patients attending a preoperative anaesthesia clinic 	<ul style="list-style-type: none"> - Improving information flow with the hospital staff and to patients - Better management of uncertainty (for example emergency). Improve the management of uncertainty by analysing historical data and describing it in the scheduling module using context data 	<ul style="list-style-type: none"> - Suggest that a solution to this would be improving the scheduling system and communicational tools at the hospital and in consideration to patient communication
<p>2 [73]</p>	<ul style="list-style-type: none"> - Gathering data on cancellations of orthopaedic surgeries 	<ul style="list-style-type: none"> - Collecting context data about the severity of the surgical need and placing it into a given group, selecting placement on waiting time list 	<ul style="list-style-type: none"> - It was suggested to have two waiting lists, one list for acute patients, and one for elective surgeries, in order to reduce cancellations - Suggests call/text reminders to patients to avoid no-shows

<p>3 [80]</p>	<ul style="list-style-type: none"> - Developing a stochastic integer programming model and integrating the model into hospital settings 	<ul style="list-style-type: none"> - Gathering context data concerning decision-making problems and what data is needed in order to solve the problems, this includes data concerning allocation, sequencing, and surgery duration - Improve the stochasticity of the system through the use of context awareness. Include department level variables that allow a better adjustment to the individual reality of each department 	<ul style="list-style-type: none"> - The model has not been implemented and there is a need for future work, but the hope is that the model could reduce cost for the hospital and provide better care for the patients
<p>3 [76]</p>	<ul style="list-style-type: none"> - Using a meta-heuristic approach integrating Pareto sets and Ant Colony Optimization (ACO) to improve resource allocations 	<ul style="list-style-type: none"> - Using algorithms to solve the scheduling problems 	<ul style="list-style-type: none"> - The model has not been implemented and there is a need for future work, but the algorithm can solve the multiple objective

		<ul style="list-style-type: none"> - Collecting data to pinpoint the needed resources to increase efficiency 	<p>surgery scheduling problem effectively according to the authors, in this way optimizing scheduling and increasing efficiency</p>
3 [72]	<ul style="list-style-type: none"> - Creating a perioperative team setup in the management of operational teams and management decisions 	<ul style="list-style-type: none"> - Using mathematic decisions to assess turnaround times, analysing what personnel is most compatible in order to avoid overtime 	<ul style="list-style-type: none"> - The thought is that stable surgical teams increased operating room efficiency which improved the turnaround times and, in this manner, contributing to avoiding operating room delays
3 [78]	<ul style="list-style-type: none"> - Developing a stochastic model as a tool for operating room scheduling and surgeon assignment. Used what they describe as “a two-step mixed integer programming model”, using a sample average approximation (SAA) method to solve the model 	<ul style="list-style-type: none"> - Collecting context data on OR block scheduling times, staff availability and surgical planning 	<ul style="list-style-type: none"> - The model has not been implemented, but the idea is that the effect will be lowering costs, increasing utilization and reducing overtime

4.5 Limitations

The literature review presented in this thesis was conducted in a systematic way, but was only reviewed by one author, therefore, it cannot be classified as a systematic review. However, attempts were made in order to minimize bias and limitations by conducting the review following the recommendations to systematic reviews [40]. The decision concerning inclusion and exclusion of articles was not controlled by another investigator. In addition, the investigator did not have previous experience regarding conducting this type of research on a master thesis level. This may lead to bias or errors. Nevertheless, the systematic nature of the study, the data extractions, and the inclusion and exclusion criteria were investigated and approved by two supervisors, both before and after the search was conducted. This, alongside with following the Cochrane Handbook's guide [40] and the PICO framework [40], could possibly make this master thesis more objective than a traditional literature review.

The method used in order to answer the research question could also be criticised because, like mentioned, in 2.2.2.1 *Selected databases*, there were some inconsistencies between the searches in Scopus and PubMed. Scopus did not allow date restricted searches, while PubMed did, this resulted in a one-month gap between the two searches. Like previously mentioned, this inequality was not discovered before the reading of titles had started. However, it was decided to investigate if there were any relevant articles among the 31 missing days in PubMed. Therefore, the same search string was investigated with the time constriction from 2018/12/01 to 2018/12/31. This search provided three articles. These articles did not include titles that seemed to be of relevance to this thesis, meaning that they would have been excluded from the research. In retrospect this was a lesson for the future, and in upcoming work, one should keep in mind that Scopus only allow year restrictions and adapt to this when conducting searches that includes the Scopus database.

Another problem encountered during the search process was a discrepancy within PubMed concerning the number of hits. This discrepancy was discovered when the investigator redid the search in PubMed to double check the results. The search in PubMed used in this thesis provided 199 articles without filters. When filters were applied 166 articles remained. The exact same search, with the same filters applied could also provide 167 articles. The explanation to this discrepancy this was unclear for some time, but after some investigations, it was discovered that there is an inconsistency in the number of search results considering if one chooses to sort the results in relation to "Best match" or "Most recent". By conducting the

exact same search, with the same filters, but selecting to sort the results in order of “Best match”, 167 articles are retrieved. While, if you chose to sort the results in order of “Most recent”, 166 articles are retrieved. There is no clear reason as to why this inconsistency occurred, and nor the investigator, nor supervisors or other staff members at NSE are able to describe why this problem occurred. In practise, it should not matter whether one chooses to sort the search result in order of “best match” or “most recent”. Given all titles would be read no matter how recent they were, or if they were considered “best match” in accordance to the query, this was not taken into account, and the discrepancy was not discovered before after the searches was retrieved. The “Sort by” selection on the computer used for conducting the search within PubMed was set to “Sort by: Most recent”: Thus, by chance, 166 articles were retrieved from PubMed. If desirable the search string for both databases can be found in Appendix B.

This thesis has no clear ethical considerations that needs to be mentioned.

4.6 Future work

In this thesis, the goal was to gather knowledge about what information would be relevant when creating a elective surgery context-aware scheduling system for hospitals. The literature review in this thesis reviled that there is a gap in research concerning the use of context data in scheduling. Most of the articles used in this review are, like in article [81], small case studies, and the quality of the studies vary greatly. In other words, there is a need for more high-quality, in-depth studies concerning this theme. This thesis is a predecessor to an upcoming systematic review on this topic. The systematic literature review will be conducted by two authors. The author declares no conflict of interest.
