Abstract. Background: In recent years, evidence has accumulated indicating that both normal and cancer cells communicate via the release and delivery of macromolecules packed into extracellular membrane vesicles. Materials and Methods: We isolated nano-sized extracellular vesicles from MYCN-amplified neuroblastoma cell lines using ultracentrifugation and exosome precipitation (Exoquick) protocols. These vesicles were characterized by transmission electron microscopy (TEM), nanoparticle tracking analysis and western blotting. Exosomal miRNA profiles were obtained using a reverse transcription-polymerase chain reaction (RT-PCR) ready-to-use panel measuring a total of 742 miRNAs. Results: In this study, we showed that MYCN-amplified neuroblastoma cell lines secrete populations of miRNAs inside small exosome-like vesicular particles. These particles were shown to be taken-up by recipient cells. By profiling the miRNA content, we demonstrated high expression of a group of established oncomirs in exosomes from two MYCN-amplified neuroblastoma cell lines. Despite the fact that other studies have demonstrated the ability of exosomal miRNAs both to repress mRNA targets and to stimulate Toll-like receptor-8 (TLR8) signaling in recipient cells, we did not observe these effects with exosomes from MYCN-amplified neuroblastoma cells. However, functional enrichment analysis reveals that miRNA targets of highly expressed exosomal miRNAs are associated with a range of cellular and molecular functions related to cell growth and cell death. Conclusion: MYCN-amplified neuroblastoma cell lines secrete exosome-like particles containing oncogenic miRNAs. This work showed for the first time that neuroblastoma cells secrete exosome-like particles containing miRNAs with potential roles in cancer progression. These findings indicate a new way for MYCN-amplified neuroblastoma cells to interact with the tumor environment.

Neuroblastoma is the most common solid tumor in children and comprises 7% of pediatric cancers. It has a clinical behavior ranging from spontaneous regression to progressive and fatal disease resistant to currently known treatments (1). In order to develop more effective treatments, a broader knowledge of neuroblastoma pathogenesis and tumor biology is needed. One of the most important prognostic factors in neuroblastoma is amplification of the MYCN oncogene, present in 20% of cases (1, 2). MYCN encodes a transcription factor (N-Myc), which contributes to a malignant phenotype through transcriptional regulation of several genes (3).

Micro-RNAs (miRNAs) are a group of small, non-coding RNAs of great importance in normal gene regulation. Aberrant miRNA expression patterns have been linked to development of many diseases, including cancer. These molecules function primarily by post-transcriptionally down-regulating gene expression by binding to the 3′ untranslated region (UTR) of messenger-RNAs (mRNAs), either by inhibiting their translation or through facilitating mRNA degradation (4). MYCN has been demonstrated to both increase and decrease the expression of oncogenic and tumor suppressive miRNAs, respectively. Several studies have investigated the role of MYCN in regulating miRNAs using RNAi-based approaches in MYCN-amplified neuroblastoma cell lines (5, 6). Other studies have used experimental over-expression of MYCN as a system for differential profiling of miRNAs (7-9). While different studies suggest that MYCN primarily functions as a suppressor of miRNA expression, it can also trans-activate the 17-92, 106a-363, 106b-25 clusters, as well as mir-9 and mir-421 through direct promoter binding (10).

Exosomes are nano-sized extracellular membrane vesicles containing several RNA species, including mRNAs and miRNAs, as well as proteins and DNA (11). Recent studies revealed that these biological macromolecules can function in intercellular communication through exosomal trafficking.
from immune cells, fibroblast and cancer cells to a range of different recipient cells (12). Exosomes originate by intraluminal budding in endosomes to form multivesicular bodies and are further transported to the cell membrane where they are released extracellularly (13). MiRNAs transported in exosomes are protected against degradation by RNases in the extracellular space and in the circulation. Exosomal miRNAs have been demonstrated not only to function through classical negative gene regulation by binding to mRNAs 3’UTR but also through stimulation of the Toll-like receptor 8 (TLR8) in humans and TLR7 in mice (14). This receptor is known to activate nuclear factor-xB (NF-xB) signaling in response to pathogen-associated RNA sequences (15). Recent investigations suggest that miRNAs, to a greater extent, allocate to intracellular vesicles with subsequent extracellular secretion when intracellular target transcripts are scarce. In an abundance of target transcripts, miRNAs tend to favor sites associated with intracellular gene silencing (16).

Cancer cell-derived exosomes can modulate a diverse array of processes, including angiogenesis (17-19), anti-tumor immune responses (11) and metastatic potential (20-22). On the other hand, non-cancer cell-derived exosomes can also act by promoting growth inhibition of malignant cells (23).

The aim of the present study was to investigate whether miRNA-containing exosomes are secreted from MYCN-amplified neuroblastoma cells. We also wanted to test if exosomes could function as intercellular players in tumorigenesis by affecting gene expression in recipient cells.

In the present study, we utilize an improved protocol for culturing cells, which yield large amounts of exosomes (24). The miRNA content of exosome-like particles from two MYCN-amplified neuroblastoma cell lines was profiled and validated. The potency of exosomes to associate with different recipient cells and regulate target seed sequences or stimulate TLR8 signaling within recipient cells was investigated. Finally, we performed functional enrichment analyses on targets of highly expressed exosomal miRNAs. Our results indicate that exosomes derived from MYCN-amplified neuroblastoma cells may have important roles in tumor development.

Materials and Methods

Cell culture. All cells were cultured at 37°C and 5% CO₂. The MYCN-amplified Kelly (ECACC, Porton Down, Salisbury, UK) and SK-N-BE(2)-C (kindly provided by Dr John Inge Johnsen, Karolinska Institutet, Stockholm, Sweden) neuroblastoma cell lines, as well as the non MYCN-amplified SK-N-AS (ATCC, Manassas, VA, USA) cell line were cultured in Roswell Park Memorial Institute medium (RPMI)-1640 containing L-glutamine and non-essential amino acids (Sigma-Aldrich, St. Louis, MO, USA). Similarly, HEK-293T (ATCC) cells were cultured in Dulbecco's modified Eagle's medium (DMEM; Sigma-Aldrich). The medium was supplemented with 10% fetal bovine serum (FBS). HEKblue-TLR8 cells (InvivoGen, San Diego, USA), stably expressing TLR8 and a reporter construct responsive to activator protein 1 (AP-1) and NF-xB activation as a readout for TLR8 stimulation, were cultured in high-glucose DMEM supplemented with 10% heat-inactivated FBS. Commercially provided HUVEC cells pooled from donors in accredited institutions (Life technologies, Carlsbad, CA, USA) were grown in medium-200 with low serum growth supplement (LSGS) (Life technologies). Consent for use of the cells in research applications was obtained from next of kin (25). Cells were split and subcultured before confluency.

The identity of the neuroblastoma cell lines used in this study was verified by short tandem repeat (STR) analysis at Center of Forensic Genetics, University of Tromsø, Tromsø, Norway. All cells used in this study were tested for mycoplasma contamination.

Isolation of exosomes. Exosome-depleted FBS was prepared by centrifugation at 4°C over night at 170,000 x g, followed by sterile filtration using 0.2 μm filters (Millipore Corporation, Billerica, MA 01821, USA). Exosome-free media (EFM) was prepared by addition of 10% exosome-depleted serum to RPMI-1640.

SK-N-BE(2)-C and Kelly cells were grown in Celline Adhere 1000 bioreactors (CLAD 1000) (Sigma-Aldrich) as previously described (24). The flasks have a small compartment for cells and a large compartment for media. A 10-kDa semi-permeable membrane that retains cells, exosomes and larger proteins, but allows exchange of nutrients and waste products, separates the two compartments. During exosome production, the medium compartment contained 500 ml complete RPMI-1640 and the cell compartment 15 ml EFM. Media from the cell compartment was collected for exosome isolation once a week. The compartment was then flushed vigorously 4 times using sterile 1× PBS, removing floating cells and other debris, before addition of fresh growth media to both compartments. After 4 isolations, adherent cells were trypsinized and checked for viability using PBS/0.4% Trypan blue staining. Exosomes were isolated by ultracentrifugation according to previously described protocols (26). Briefly, conditioned media was centrifuged at 200xg for 10 minutes, 2,000xg for 20 minutes, 10,000xg for 30 minutes and 110,000xg for 70 minutes to remove cells, debris and microvesicles, respectively. Unconditioned exosome-free media (EFM) was treated in parallel as a negative control. The amounts of exosomes isolated were measured using the Bio-Rad DC protein assay (Bio-Rad, Hercules, CA, USA) and stored at –80°C or directly used in experiments.

Western blotting. Cells and exosomes were lysed in RIPA buffer (50mM Tris HCl, pH 8, 150 mM NaCl, 1% NP-40, 0.5% sodium deoxycholate, 0.1% SDS) supplemented with protease inhibitor cocktail (Roche Applied Science, Indianapolis, IN, USA). Thirty μg proteins were separated on NuPAGE 4-12% Bis-Tris Gels (Life technologies). Proteins were transferred onto Immobilon-FL polyvinylidene difluoride (PVDF) membranes (Millipore Corp., Bedford, MA, USA), blocked for 1 hour at room temperature in Odyssey Blocking Buffer (LI-COR, Lincoln, NE, USA) before incubation at 4°C overnight with the primary antibodies CD9 sc-13118, CD63 sc-5275, GAPDH sc-25778, N-MYC sc-53113 (Santa Cruz, Dallas, TX, USA), TSG101 ab83 (Abcam, Cambridge, UK), GRP78 G8918, Actin A2066 (Sigma-Aldrich). Secondary antibodies were goat anti-rabbit IRDye800CW (Rockland, Gilbertsville, PA, USA) and goat anti-mouse Alexa Fluor 680 (Life technologies). Antibody binding was detected using the Odyssey Infrared Imaging System (LI-COR).
Characterization of the size and morphology of isolated particles using transmission electron microscopy (TEM) and Nanosight analysis. Exosome samples isolated by ultracentrifugation were washed, re-suspended in PBS and fixed in 2% paraformaldehyde (PFA). Subsequently, samples were loaded on formvar-coated electron microscopy (EM) grids. After washing, the samples were post-fixated in 1% gluteraldehyde. They were washed once more and, subsequently, stained in methyl cellulose-uranyl acetate for 10 min on ice. Grids were dried and examined using TEM at 80,000× magnification.

Isolated exosomes were further analyzed using the Nanosight LM10 system equipped with a 405 nm blue laser (Nanosight Ltd, Wiltshire, UK). The laser illuminated the isolated vesicles and the software recorded their movement under Brownian motion. Videos were subjected to nanoparticle tracking analysis using the provided software to acquire size distribution. All analysis parameters were kept constant within the experiments.

Profiling of exosomal miRNAs. Exosomal miRNA content was profiled from SK-N-BE(2)-C and Kelly cells. All miRNA assays were run in at least two biological isolates. Exosomes were isolated as specified and lysed in Qiazol reagent (Qiagen, Valencia, CA, USA). RNA was precipitated using isopropanol. RNA concentration was determined using the Qubit 2.0 RNA assay kit (Life technologies). The content and quality of the exosomal RNA was determined using the 2100 Bioanalyzer instrument with the small RNA and Eukaryote total RNA kits (Agilent technologies, Santa Clara, CA, USA). Forty ng total RNA was reverse transcribed using the miRCURY universal cDNA synthesis kit (Exiqon, Copenhagen, Denmark). RNA from exosomes and cells was profiled with the
miRCURY qPCR panels 1+2 V2.M (Exiqon, Copenhagen, Denmark). ROX was included as a passive reference dye. Variations between plates were normalized using interplate calibrators and cycle threshold (C_T) values were, then, averaged between replicates. Unconditioned EFM was also profiled to determine background signal. C_T values <35 were considered detected. We included miRNA assays where the C_T value of the EFM control was >35, indicating no interfering bovine miRNAs. However, samples were included if (C_T EFM)−(C_T sample) >6.6, indicating a bovine background of less than 1% of the sample expression.

To further validate the origin of the isolated miRNAs, Kelly exosome preparations were obtained in parallel using both differential centrifugation and the Exoquick-TC polymer-based exosome precipitation solution. Exoquick isolation was performed according to the manufacturer’s protocol (System Biosciences, Mountain View, CA, USA). Equal amounts of RNA were used as input and a spike in control was added before cDNA synthesis. The relation between the different isolation methods were compared and presented as ΔC_T normalized to the spike in (C_T spike-in−C_T miRNA). Individual miRNA primer assays (Exiqon) for mir-106a, mir-20a, mir-92a and a spike-in control were used to measure miRNA expression. Student’s t-test statistics was used when comparing the isolation methods.

Figure 2. miRNA expression in neuroblastoma exosome-like extracellular particles. A) Venn diagram of miRNAs expressed in exosomes from Kelly and SK-N-BE(2)-C cells (left). Average C_T values of miRNA assays in exosomal samples (right) from Kelly and SK-N-BE(2)-C cells. miRNAs commonly expressed among the top 25 in both cell lines constitute the overlapping fraction in the Venn diagram and are marked by a circle (o) in the table. B) The relative expression of three different miRNAs were measured in exosomal isolates from Kelly cell using two different isolation protocols (Exoquick and ultracentrifugation). ΔC_T = (C_T miRNA assay−C_T spike-in). C) ΔC_T values in untreated samples (NO-set to 0), RNase and RNase+Triton X-100 treated samples. Untreated samples were used as calibrators and set to zero. Increases in ΔC_T (compared to untreated samples-NO) indicate degradation in response to the treatment. Exosomes isolated from Kelly cells. Error bars indicate standard deviation. ns illustrates *p>0.05, **p<0.05, 0.01 and ***p<0.001.
miRNA responsive luciferase assays. HEK-293T and SK-N-AS cells were used to measure uptake of functional miRNAs. For transfection, we used 1 μl/ml Lipofectamine 2000 (Life sciences) according to the manufacturer’s instructions. Cells were co-transfected with the pMIR-report firefly-luciferase reporter vector (Promega, Madison, WI, USA) containing miRNA responsive seed sequences and the constitutively Renilla luciferase expressing vector pRL-TK (Promega). miRNA mimics targeting the relevant seed in the reporter vector and a scrambled control miRNA were used as positive and negative controls, respectively (Shanghai genepharma, Shanghai, China). The mir-92a insert was created by annealing the primers 5’-CTAGTATCTGG ACCAGGCTTGGGTAGATGGTCAATAGAATAGCTA-3’ (sense) and 5’-AGCCTATTTCTATGTGACATCTACCCACAGCCTG GTCCAGATA-3’ (antisense), corresponding to the mir-92a binding site of the DKK3-3’UTR (27). The annealed primers were ligated into SpeI/HindIII-treated pMIR-Report vector to generate a mir-92a responsive firefly luciferase construct (pMIR-92a). Similarly, the pMIR-report-derived pMIR-9 (18) and pMIR-21-luc (kindly provided gift From Dr. Anders H. Lund, Copenhagen) vectors contain 3’UTR binding sites for mir-9 and mir-21 downstream of the firefly luciferase coding sequence. One-way ANOVA with Tukeys post-test was used when comparing the treatments.

TLR8 activation assay. One hundred thousand human HEKblue-TLR8 cells (Invivogen) were seeded in each 4 cm² well. Twenty-four hours after addition, cells subjected to exosomes were examined using immunofluorescence microscopy and flow cytometry.

Figure 3. Uptake of labeled exosomes in recipient cells. A) HEK-293T cells exposed to PKH67 (green)-labeled Kelly exosomes (KELLYexo) and EFM control. Pictures were taken at 400x magnification. B) Flow cytometry analysis of SK-N-AS cells exposed to fluorescent exosomes (KELLYexo) or controls (Blank=no treatment, EFM=exosome-free media).

Figure 4. Reporter activity for different exosomal miRNAs and ELISA for the mir-92 target DKK3 after treatment with exosomes. A) SK-N-AS cells expressing reporter constructs containing binding sites for no human miRNAs (pMir-Control), mir-92 (pMir-92a), mir-9 (pMir-9) and mir-21 (pMir-21) were incubated with the corresponding miRNA mimics (40 pmols). Mimics without human targets (NC) (40 pmols) were used as negative controls. Luciferase activity was measured 24 h after transfection. RLU=relative luciferase units. B) Same as A, except 40 µg/ml isolated exosomes from Kelly (KELLYexo), SK-N-BE(2)-C (SKNBEexo) or control isolates (EFM control) were added to the transfected cells instead of miRNA mimics. C) Optical density (OD) measurements of culture media from HEKblue-TLR8 cells containing AP-1 and NF-kB responsive SEAP-expressing elements. Cells were stimulated with positive controls r848 (5μg) or ssRNA40 (5μg), SK-N-BE(2)-C exosomes (SKNBEexo), EFM exosome control and untreated. Error bars indicate standard deviation. ns indicates p>0.05, *p<0.05.
after seeding, the cells were treated with exosomes (50 μg/ml) from SK-N-BE(2)-C cells. As positive controls, parallels were either transfected with 5 μg/ml of the viral ssRNA40 using 2 μL/ml Lipofectamine 2000 (Life sciences) or maintained in the presence of the molecular agonist R848 (5 μg/ml). Twenty hours after treatment, the media was harvested and centrifuged at 21,100 × g for 5 min to remove debris and secreted embryonic alkaline phosphatase (SEAP) levels in the supernatant was quantified using the QuantiBlue assay (InvivioGen, San Diego, CA 92121, USA). The data were statistically analyzed using one-way ANOVA with Tukey's post-test.

**Results**

**MYCN-amplified neuroblastoma-derived particles exhibit exosome-like characteristics.** To determine if MYCN-amplified neuroblastoma cells secrete exosome-like vesicles, we isolated extracellular vesicles by a standard ultracentrifugation protocol from in vitro cultured Kelly and SK-N-BE(2)-C cells. Transmission electron microscopy and Nanosight size distribution analysis demonstrated a population of small circular particles between 50 to 350 nm, with a mode of 172 nm (Figure 1A and B). The EFM control media did not contain measurable levels of particles (data not shown). Western blot analysis demonstrated a striking enrichment of the tetraspanin exosomal markers CD63 and CD9. A more modest enrichment of another exosomal marker, TSG101, was seen. In contrast, the endoplasmic reticulum marker GRP78, the cytoskeletal component β-actin and the N-myc protein were almost exclusively detected in cellular lysates (Figure 1C). RNA composition analysis using a Bioanalyzer revealed that the exosome-like particles were highly enriched in small RNAs less than 300-400 nucleotides (nt). In contrast to cellular RNA, they also lacked cellular 18S and 28S ribosomal peaks, identifying the RNA composition...
Table 1. IPA pathway analysis of neuroblastoma exosomal miRNA targets genes. Enriched functional categories as reported by IPA from the target genes for the 25 highest expressed miRNAs isolated from SK-N-BE(2)-C and Kelly cells. Number of molecules indicates potential miRNA target genes linked to each category. Range p-value shows the lowest and highest p-values from all under-categories.

Neuroblastoma exosomes associate with various recipient cells. To investigate if recipient cells take-up the isolated exosome-like particles, fluorescently labeled exosomes were added to cultured HEK-293T cells and tracked by microscopy. HEK-293T cells displayed significant uptake of labeled Kelly-derived exosomes after 24 h co-incubation (Figure 3A). Flow cytometry analysis of SK-N-AS (Figure 3B) cells similarly demonstrated exosome uptake, as measured by increased recipient cell fluorescence. Similar uptake in other cell lines tested, including HUVEC, SK-N-BE(2)-C and Kelly cell lines, was verified by both fluorescence microscopy and flow cytometry suggesting a wide range of potential recipient cells, including an autocrine uptake.

Exosomal miRNAs do not repress target gene expression or activate the endosomal TLR8 receptor in recipient cells. Mir-92a was the most highly expressed miRNA when considering exosomes from both cell lines examined. To investigate whether miRNA-containing exosomes could regulate established 3’UTR target seed-sequences in recipient cells, we transfected cells with miRNA sensing luciferase reporter vectors. Luciferase activity was significantly reduced after co-transfection with purified miRNA mimics (Figure 4A). However, we did not observe any significant differences in luciferase activity using mir-92a (pMIR-92a), mir-9 (pMIR-9) and mir-21 (pMIR-21-luc) responsive constructs when exposing SK-N-AS or HEK-293T cells to 40 μg/ml Kelly or SK-N-BE(2)-C exosomes. (Figure 4A).

Finally, we tested the recent finding that exosomal miRNAs may induce NF-kB activation through TLR8 activation. We stimulated HEKblue-TLR8 cells stably transfected with TLR8 and NF-kB/AP-1 SEAP reporter constructs with exosomes and controls. In contrast to the positive controls ssRNA40 and r848, SK-N-BE(2)-C exosomes did not give significant increases in SEAP levels compared to untreated cells (Figure 4C).

Functional enrichment analysis indicates that miRNAs from neuroblastoma exosomes are associated with signal pathways important for cell growth, survival and death. To evaluate the functions of miRNAs from neuroblastoma cell-derived exosomes, we used the IPA software to predict mRNA targets and performed a functional enrichment analysis on these predicted targets.

The 25 most abundantly expressed miRNAs from Kelly and SK-N-BE(2)-C exosomes were predicted to target 565 and 499 experimentally observed mRNAs, respectively. Furthermore, when these miRNAs were analyzed for functional categories, a range of cellular and molecular functions related to cell development, growth and death were identified (Table 1).

When IPA was further used to analyze canonical pathways, we identified “Molecular Mechanisms of Cancer” (SKNBE2exo: \( p=8.8\times10^{-30} \ n=59 \), KELLYexo: \( p=6.4\times10^{-29} \ n=62 \), in addition to several well-characterized pathways like as fundamentally different from their cells of origin (Figure 1 D, left panel). Analysis of small RNAs revealed a population of RNAs at about 23 nt, consistent with the expected size of miRNAs. In combination, these results confirm successful isolation of exosome-like particles from neuroblastoma cells.

**MYCN-amplified neuroblastoma cells secrete exosome-like particles with a distinct miRNAs content.** The miRNA content of exosome-like particles from MYCN-amplified neuroblastoma cell lines Kelly and SK-N-BE(2)-C was investigated using LNA-qPCR arrays. The top 25 expressed exosomal miRNAs isolated from both cell lines were compared and 11 of the exosomal miRNAs identified (mir-16, 125b, 21, 23a, 24, 25, 27b, 218, 320a, 320b and 92a) were common to both cell lines (Figure 2A, marked by circles).

To validate the origin of the assayed miRNAs, we compared the expression of three different miRNAs from Kelly exosomes using two different exosome isolation protocols. The Exoquick-TC and the ultracentrifugation exosome-isolates had almost identical expression of the three assayed miRNAs, mir-20a, mir-92a and mir-106b (Figure 2B). Furthermore, we investigated whether the secreted miRNAs were in fact resistant to RNAse mediated degradation. Kelly-derived exosomes were treated with RNase in the presence or absence of Triton X-100 and the degradation was further enhanced by addition of the detergent 1% Triton-×100 (Figure 2C).

Collectively, these results strongly suggest that the miRNAs investigated are indeed present within the isolated exosome-like particles.
aryl hydrocarbon receptor- (SKNBE2exo: p=1.9×10^{-19} n=30, KELLYexo: p=8.0×10^{-23} n=35), apoptosis- (SKNBE2exo: p=4.9×10^{-18} n=24, KELLYexo: p=1.9×10^{-14} n=22), p53- (SKNBE2exo: p=5.7×10^{-18} n=25, KELLYexo: p=1.5×10^{-17} n=26), cell cycle (G1/S checkpoint)- (SKNBE2exo: p=3.0×10^{-14} n=18, KELLYexo: p=1.1×10^{-16} n=21), STAT3- (SKNBE2exo: p=2.7×10^{-15} n=20, KELLYexo: p=2.4×10^{-16} n=22) and PTEN- (SKNBE2exo: p=6.7×10^{-16} n=25, KELLYexo: p=2.1×10^{-15} n=26) signaling, to be the most significantly enriched pathways by the predicted miRNA targets (Figure 5). The full list of putative targets related to all significant pathways for both SK-N-BE(2)-c and Kelly exosomal miRNAs can be provided upon request.

Discussion

The aim of our study was to identify and profile exosomal miRNAs from MYCN-amplified neuroblastoma cells and to investigate their role in intercellular signaling by tumor cells.

The present data show that MYCN-amplified neuroblastoma cells secrete a population of small vesicles exhibiting the characteristics of exosomes. Enrichment of established exosomal markers like CD63, CD9 and TSG101, and absence of intracellular GRP78, β-actin and N-myc proteins provide further support for this conclusion. Previously, a full proteomic analysis of neuroblastoma-derived exosomes showed that, in addition to the exosomal markers, exosomes from neuroblastoma cells, also express proteins involved in defense response, cell differentiation, cell proliferation and regulation of other important biological processes, including the neuroblastoma specific marker GD2 disialoganglioside (28).

To further characterize the secreted vesicles, we performed nanoparticle tracking analysis using Nanosight and TEM and showed a size distribution of these particles similar to that found in exosome isolates (29-31). In addition, the enrichment in small RNAs and relatively low content of ribosomal RNA is also a previously described trait of exosomes. The RNA profiles identified in our samples match the findings in the two most in-depth descriptions of exosomal RNA content (32, 33). The authors of these articles used deep sequencing approaches and identified significant enrichments of small RNAs not restricted to and, in fact, not dominated by miRNAs. They also observed large amounts of Y-RNAs in the exosomes. We incidentally discovered high expression of a Y-RNA, previously believed to be a miRNA (mir-1979) (34) in exosomes from both Kelly and SK-N-BE(2)-C (average C_T of 22.2 and 21.1, respectively). The RNA distribution profiles of our exosome preparations clearly indicate larger populations of small RNAs in addition to the observed band corresponding to the size of miRNAs (20-25 nt). These different RNAs may have yet un-identified important functions. Deep sequencing approaches could be utilized in order to map for the complete transcriptome of these small vesicles.

By profiling the exosomal miRNA content, we identified a population of 11 miRNAs highly expressed from both screened cell lines. These miRNAs included several known oncogenic miRNAs. Recipient cells were associated with fluorescently stained exosomes after 24 h co-incubation, indicating uptake. However, luciferase reporter studies on mir-92a, mir-9 and mir-21 in cells exposed to exosomes did not yield any reduction in reporter activity in recipient cells. This was the case, even after addition of 40 μg/ml neuroblastoma exosomes, compared to 12.5 μg/ml exosomes in a comparable study (35).

Our experiments indicate that exosomal mir-92a, mir-9 and mir-21 do not have functional effects on established mRNA 3’UTR seed targets in the tested recipient cells, at least not without some co-stimulatory factor not yet identified. The recent finding that exosomal miRNAs can stimulate NF-KB signaling through binding and activating TLR8 in cellular endosomal compartments does not seem to be relevant with exosomes from MYCN-amplified neuroblastoma cells.

In order to obtain information regarding the potential role of the neuroblastoma-derived exosomal miRNAs, we performed a functional enrichment analysis using predicted mRNA target genes from the 25 highest expressed miRNAs. One of the highest scores was obtained for AHR signaling, shown to be involved in multiple aspects of cancer like survival, proliferation, differentiation, apoptosis, angiogenesis and invasion, reviewed in Feng et al. (36). Very recent data suggest that AHR is inversely correlated to MYCN expression in neuroblastoma tissue. Ectopic over-expression of AHR suppressed MYCN promoter activity resulting in down-regulation of MYCN expression, while AHR shRNA promoted the expression of E2F1 and MYCN in neuroblastoma cells. AHR was suggested to be an important upstream regulator of MYCN (37).

The analyses further revealed that several canonical pathways known to be deregulated in most cancers are potentially impacted by the exosomal miRNAs. These include apoptosis-, p53- and G1/S checkpoint regulation signaling. Aberrant STAT3 signaling is well-known to promote initiation and progression of several human cancers by either promotion of cell proliferation, survival, invasion, metastasis and angiogenesis, or inhibiting apoptosis (38). Recently, a critical role for STAT3 in metastatic drug resistant neuroblastoma was documented (39). Several reports during the last years have also established the importance of PTEN/PI3K/Akt signaling, including its relation to MYCN, in neuroblastoma survival, proliferation, invasion and angiogenesis (40-43).

The tropism and uptake of exosomes into different cells have been debated, but is believed to involve surface receptors (13). In contrast to other studies demonstrating direct seed interaction by exosomal miRNAs, we were not able to show any significant effects in recipient cells using our miRNA
reporter assays. A recent study performed on immune cells demonstrated that exosome substitution alone was not enough for effects on miRNA reporters in recipient cells. Cell-to-cell contact and the subsequent formation of an immunological synapse were required for functional transmission of functionally active miRNA contents (44). Another recent study demonstrates that the lipid raft-associated Caveolin1 (CAV1) can inhibit uptake and function of exosomes by inhibiting ERK1/2 (29). It has also been demonstrated that phagocytic cells have a high uptake of exosomes, while the non-phagocytic cells only associate with exosomes without internalizing them (45). Considering these observations, it is not unlikely that the cell systems used in our studies lack the specific prerequisite conditions for exosomal miRNA function.

**Conclusion**

In this article, we present data demonstrating the secretion of exosome-like particles from two well-studied MYCN-amplified neuroblastoma cell lines. The exosomes are internalized into recipient cells and contain miRNAs with known oncogenic properties. Exosomal miRNAs may have roles in cell-to-cell signaling in neuroblastoma pathogenesis. However, our data do not support the theory that this happens through miRNA-seed sequence interaction or by activating the TLR8 receptor, as previously described in model systems of other cancers.
