A Quantitative Analysis of Colonic Mucosal Oxylipins and Endocannabinoids in Treatment-Naïve and Deep Remission Ulcerative Colitis Patients and the Potential Link With Cytokine Gene Expression

Joseph Diab, MSc,* Rania Al-Mahdi, PhD,† Sandra Gouveia-Figueira, PhD,‡ Terkel Hansen, PhD,* Einar Jensen, PhD,* Rasmus Goll, PhD,† Thomas Moritz, PhD,‡ Jon Florholmen, PhD,† and Guro Forsdahl, PhD*

Background: The bioactive metabolites of omega 3 and omega 6 polyunsaturated fatty acids (ω-3 and ω-6) are known as oxylipins and endocannabinoids (eCBs). These lipid metabolites are involved in promoting and resolving the inflammatory response that leads to the onset of inflammatory bowel disease (IBD). This study aims to quantify these bioactive lipids in the colonic mucosa to evaluate the potential link to cytokine gene expression during inflammatory events in ulcerative colitis (UC).

Methods: Colon biopsies were taken from 15 treatment-naïve UC patients, 5 deep remission UC patients, and 10 healthy controls. Thirty-five oxylipins and 11 eCBs were quantified by means of ultra-high-performance liquid chromatography coupled with tandem mass spectrometry. Levels of mRNA for 10 cytokines were measured by reverse transcription polymerase chain reaction.

Results: Levels of ω-6-related oxylipins were significantly elevated in treatment-naïve patients with respect to controls, whereas the levels of ω-3 eCBs were lower. 15S-Hydroxy-eicosatetraenoic acid (15S-HETrE) was significantly upregulated in UC deep remission patients compared with controls. All investigated cytokines had significantly higher mRNA levels in the inflamed mucosa of treatment-naïve UC patients. Cytokine gene expression was positively correlated with several ω-6 arachidonic acid–related oxylipins, whereas negative correlation was found with lipoxin, prostacyclin, and the eCBs.

Conclusions: Increased levels of ω-6-related oxylipins and decreased levels of ω-3-related eCBs are associated with the debut of UC. This highlights the altered balance between pro- and anti-inflammatory lipid mediators in IBD and suggests potential targets for intervention.

Key Words: EPEA, DHEA, IBD, PUFA, eicosanoids

INTRODUCTION

Inflammatory bowel disease (IBD) is a chronic, relapsing inflammatory disorder in the gastrointestinal tract that affects up to 0.5% of the population of the Western world. The 2 major forms of IBD, ulcerative colitis (UC) and Crohn’s disease (CD), are characterized by a dysregulated mucosal immune response triggered by intestinal commensal flora. The onset of IBD symptoms appears to be caused by an imbalance between pro- and anti-inflammatory molecules. However, several factors might be involved in the chronic inflammatory state observed in IBD. These include cytokines, interleukins (ILs), nitric oxide (NO), free radicals, activated Toll-like receptors, oxylipins, and microbiota. Furthermore, it has previously been shown that colitis is associated with a disruption in the lipid metabolism.

Oxylipins are bioactive derivatives mainly from omega 3 and omega 6 polyunsaturated fatty acids (ω-3 and ω-6 PUFAs) such as ω-6 arachidonic acid (AA), ω-6 linoleic acid (LA), ω-3 eicosapentaenoic acid (EPA), and ω-3 docosahexaenoic acid (DHA). Oxylipins are synthesized through 3 main enzymatic pathways, namely cyclooxygenase (COX), lipooxygenase (LOX), and cytochrome P450 (CYP450), resulting in more than 100 active mediators. The AA-derived oxylipins, also known as eicosanoids, are involved in chemotaxis and promoting the recruitment of neutrophils to the site of inflammation. The role of oxylipins in IBD is very complex and not completely understood; for example, prostaglandin E2 (PGE2) induces epithelial proliferation in response to mucosal damage and suppresses the release of tumor necrosis factor (TNF) from macrophages.
Leukotriene B4 (LTB4) has chemotactic effects by stimulating leucocyte activation and adhesion to the vascular endothelium and promotes the production of inflammatory cytokines. Furthermore, inflammation-resolving oxylipins terming resolvins, lipoxins, protectins, and maresins are produced from AA, EPA, and DHA.

The endocannabinoids (eCBs) are a family of bioactive lipids that are biosynthesized from membrane glycerophospholipids and bind to cannabis receptors (CB), specifically, CB1 and CB2. The primary eCBs are arachidonoyl ethanolamine, known as anandamide (AEA), and 2-arachidonoylglycerol (2-AG). The secondary or “atypical” eCBs, such as docosahexaenoic ethanolamine (DHEA) and eicosapentaenoyl ethanolamide (EPEA), play an important synergistic role to AEA. CB1 receptors are highly expressed in several brain regions that mediate the psychoactive effects of cannabinoids, whereas CB2 receptors are found in a number of immune cells and in a few neurons. It has been shown that eCBs regulate immune homeostasis in the gut–pancreas axis. For instance, eCBs inhibit the release of a wide class of pro-inflammatory mediators, including IL-1β, TNF-α and NO. Some studies have reported changes in endocannabinoid system expression during UC. However, a previous targeted analysis of eCBs in inflamed mucosa in IBD was inconclusive and was restricted to ω-6 AA derivatives.

A quantitative analysis of all bioactive lipid metabolites in UC colon biopsies is needed to fully understand their involvement in promoting and resolving the inflammatory event in IBD. Therefore, in this study, we have quantified 35 nonesterified oxylipins and 11 eCB metabolites (Supplementary Table 1) simultaneously in colon biopsies taken from 3 different groups, namely treatment-naive UC patients in the debut of the disease, deep remission UC patients, and healthy subjects. We have further analyzed the cytokine profile in colon biopsies from the same patients to evaluate a potential link between the lipid profile and the inflammatory events mediated by pro- and anti-inflammatory cytokines.

**METHODS**

**Collection of Biopsies**

Mucosal biopsies were collected from newly diagnosed treatment-naive UC patients and UC patients in deep remission. UC diagnosis was established based on clinical, endoscopic, and histological criteria defined by European Crohn’s and Colitis Organization (ECCO) guidelines. Furthermore, the degree of inflammation was evaluated during colonoscopy using the scoring system of the Ulcerative Colitis Disease Activity Index (UCDAI). Moreover, TNF mRNA levels were measured by real-time reverse transcription polymerase chain reaction (RT-PCR) to assess the level of UC activity. Deep remission was defined by endoscopically healed mucosa (Mayo score = 0) and a normalized mucosal TNF gene expression level induced by anti-TNF treatment. Subjects admitted for a cancer screening and with normal colonoscopy histological findings served as healthy controls. None of the recruited subjects suffered from irritable bowel syndrome, and they were not taking nonsteroidal anti-inflammatory drugs (NSAIDs) before the colonoscopy. The patients in deep remission were on regular UC medications including 5-aminosalicylic acid (5-ASA), azathioprine, and anti-TNF. From each study participant, 2 adjacent biopsies were obtained from the inflamed mucosa, and 1 biopsy was immediately immersed in RNAlater (Qiagen, Hilden, Germany). The second biopsy was immediately frozen in a dry cryotube tube at −70°C. The biopsies from both UC patients and the UC remission group were obtained from the rectum or sigmoid colon, whereas biopsies from the control group were obtained from the rectum area only. The dry weight of the biopsies ranged from 2 to 8 mg. All biopsies were kept at −70°C until further analysis.

**Chemical and Reagents**

The eCB analytical standards, the oxylipin analytical standards, and 12- (cyclohexylamino)carbonyl[amino]-dodecanoic acid (CUDA) were purchased from Cayman Chemicals (Ann Arbor, MI, USA). Acetonitrile (ACN) and methanol (MeOH) were acquired from Merck (Darmstadt, Germany). Acetic acid was purchased from Aldrich Chemical Company, Inc. (Milwaukee, WI, USA). All solvents were of HPLC grade or higher. Water was purified by a Milli-Q Gradient system (Millipore, Milford, MA, USA). Oasis HLB cartridges (3 cc, 60 mg) were obtained from Waters (Milford, MA, USA).

**Endocannabinoid and Oxylipin Quantification**

Analysis of eCBs and nonesterified oxylipins was performed by a previously published method. Briefly, 500 µL of methanol and a tungsten bead were added to each sample; the samples were then mixed in Qiagen plates (Qiagen, Valencia, CA, USA) for 3 minutes at a speed of 30 Hz. After removing the beads, the samples were centrifuged for 3 minutes at a speed of 14,000 rpm (2125 × g) and +4°C. The metabolites were extracted by a solid phase extraction (SPE) protocol described elsewhere. In brief, the samples were spiked with 10 µL of the following internal standard solution: 50 ng/mL 12,13-DiHOME-d₄ and 12,13-EPOME-d₄, 25 ng/mL 9-HODE-d₄, PGE₂-d₄, 5-HETE-d₄, 20-HETE-d₄ and TXB₂-d₄, 800 ng/mL 2-AG-d₆, 40 ng/mL PGF₂α, EA-d₄ and PGE₂-EA-d₄, 20 ng/mL AEA-d₄, OEA-d₄, and SEA-d₄. Then, the samples were applied to the SPE columns and washed by a mix of 5% MeOH and 0.1% acetic acid, before eluting the metabolites with 3 mL of ACN and 2 mL of MeOH. Finally, the samples were dried using a vacuum concentrator (MIVac, SP, Warminster, PA, USA), reconstituted in 100 µL of MeOH, and spiked with 10 µL of the recovery standard CUDA (0.025 µg/mL).
Quantification of Cytokine mRNA Using Real-time PCR

Total RNA was isolated from patient biopsies using the Allprep DNA/RNA Mini Kit (Qiagen, Hilden, Germany, Cat No: 80204) and the automated QIAcube instrument (Qiagen, Hilden, Germany) according to the manufacturer’s recommendations. Quantity and purity of the extracted RNA were determined using the Qubit 3 Fluorometer (Cat No: Q33216; Invitrogen by Thermo Fisher Scientific, Waltham, MA, USA). Reverse transcription of the total RNA was performed using the QuantiTect Reverse Transcription Kit (Cat. No: 205314; Qiagen, Hilden, Germany). Levels of mRNA for IL-1β, IL-4, IL-5, IL-6, IL-10, IL-12, IL-17, IL-23, IFN-γ, TNF, and the housekeeping gene β-actin were quantified by a previously published method.24 The primers and probe sequences are shown in Supplementary Table 3. Cytokine mRNA expression was reported according to the ∆CT and ∆∆CT method described by Schmittgen, with fold change as $2^{-\Delta\Delta CT}$.25 For the TNF assay, we reported according to the ∆CT and ∆∆CT method described by Schmittgen, with fold change as $2^{-\Delta\Delta CT}$.25

Statistical Analysis

The concentration of each metabolite was normalized by sample weight, and the results were reported as pg/mg of colon tissue. Statistical analysis was carried out using MetaboAnalyst 3.0, a web tool for metabolomics data analysis (http://www.metaboanalyst.ca/).26 Two samples had extremely low and high concentrations (below/higher than the mean plus/minus 3 standard deviations) of 60% of the metabolites and were consequently excluded. One percent of reported metabolites were below the level of detection. Therefore, they were replaced by a small value (half of the minimum positive value in the original data).

RESULTS

Subjects Characteristic

In total, 15 newly diagnosed treatment-naïve UC patients with mild to severe disease activity, 5 UC patients in deep remission, and 10 healthy controls were enrolled in this study. The study group characteristics are described in Table 1. Ulcerative colitis patients’ disease activity ranged from mild to severe; a UCDAI score of 3 to 6 was defined as mild, 7 to 10 as moderate, and 11 to 12 as severe UC. Accordingly, 7 patients had mild UC, 4 patients had moderate UC, and 4 patients had severe UC.
Mucosal eCB and Oxylipin Profiles in Treatment-Naïve UC Patients, UC Remission Patients, and Controls

The concentrations of eCBs and oxylipins in colon biopsies from treatment-naïve UC and deep remission UC patients were compared with controls. As seen in Figure 1A, the volcano plot shows that the mucosal levels of PGE$_2$, thromboxane (TXB$_2$), trans-leukotriene (trans-LTB4), and 12-Hydroxy-eicosatetraenoic acid (12-HETE) were significantly upregulated (FDR ≤ 0.1) in colon biopsies taken from treatment-naïve patients. The mean concentrations of these oxylipins were increased by 7-, 3-, 8-, and 5-fold, respectively. In contrast, DHEA and EPEA were significantly downregulated. The mean concentration was decreased by 3-fold for both eCBs, with respect to the control group.

The comparison between the mucosal concentration of the investigated metabolites in deep remission UC patients and healthy controls is demonstrated in Figure 1B. Only 15S-Hydroxy-eicosatetraenoic acid (15s-HETE) was significantly upregulated by 2-fold in deep remission UC patients compared with healthy controls.

Furthermore, the Kruskal-Wallis test was used to compare the metabolite mucosal profiles between all 3 groups, as shown in Figure 2A. The metabolites that showed significant variance between the study groups were 1 ω-3 eCB, specifically DHA (Fig. 1D, C), and 1 ω-6 AA oxylipin, specifically HETE-12 (Fig. 1D). The mean concentration of DHA decreased in a stepwise manner from UC-naïve treatment patients to UC remission patients and controls. In contrast, the concentration of HETE-12 was the highest in the treatment-naïve UC group.

Mucosal Cytokine Gene Expression in Treatment-Naïve UC Patients, UC Remission Patients, and Controls

Cytokine gene expression in colon biopsies was investigated by the quantification of mRNA using real-time PCR. Comparative analysis of mean differences in the cytokine gene expression levels between treatment-naïve UC patients, UC remission patients, and controls was done by Student’s t-test. The results are shown in Table 2. All investigated cytokines had significantly higher mRNA levels in the inflamed mucosa of treatment-naïve UC patients compared with healthy controls. However, IL-5 did not differ significantly (P = 0.057). Furthermore, no significant differences were found in the gene expression of all investigated cytokines between the UC remission group and healthy controls (Table 2).

Cytokine Gene Expression Correlation With Oxylipins and eCBs

To assess the association between cytokine gene expression and the investigated metabolites in the mucosal biopsies of the study groups, Spearman’s rank correlation between cytokines-cytokines and cytokines-metabolites was computed and is presented as an asymmetric heatmap (Fig. 2), where red represents a positive correlation and blue a negative correlation. All investigated cytokines were positively correlated with each other. Furthermore, the cytokines were found to be negatively correlated with several eCBs, mainly EPEA and DHEA (r = –0.4). In contrast, the cytokines were positively correlated with nearly all AA metabolites, specifically PGE$_2$, 12-HETE, 5-Hydroxy-eicosatetraenoic acid (5-HETE), TXB$_2$, and LTB$_4$ (r = 0.5). However, there was a negative correlation with lipoxin (LXA$_3$) and α-Keto prostaglandin F$_3$ (α-keto PGF$_3$), as shown in Figure 2. Furthermore, the correlation matrix revealed a negative correlation between cytokines and ω-6 AA-derived vicinal diols (DHETs) and a positive correlation with ω-6 AA-derived epoxides (EpETrEs).

Spearman’s rank correlation coefficients were computed for metabolites-metabolites, cytokines-cytokines, and cytokines-metabolites and are represented as a symmetric heatmap (Supplementary Fig. 1). In addition, the correlation coefficients and the significance P values corresponding to all computed correlations are provided in the Supplementary Data.

**DISCUSSION**

This study provides a unique, quantitative, and comprehensive analysis of a large number of oxylipins and eCBs in the colon mucosa of treatment-naïve newly diagnosed UC patients and deep remission UC patients. Previous studies were restricted to investigating oxylipins related to selected enzymatic pathways (COX-2 and 5-LOX) in UC. Moreover, in these studies, oxylipins were determined by liquid chromatography–tandem mass spectrometry (LC-MS/MS) untargeted analysis. For a more accurate quantification, we have quantified 35 oxylipin and 11 eCB metabolites using a fully validated

FIGURE 1. Results from univariate analysis of oxylipin and eCB mean mucosal concentrations. A, B, Volcano plots of changes in mean mucosal concentrations of oxylipins and eCBs in treatment-naïve patients vs healthy controls (HCs), and UC deep remission patients vs HCs, respectively. The vertical lines correspond to 2.0-fold up- and downregulation, and the horizontal lines represent a \( P \) value of 0.05 (Mann-Whitney \( U \) test) at a cutoff FDR value of 0.1. The points in the plots represent metabolite mean concentrations. Metabolites in pink have passed the volcano plot filtering. C, D, Box plots of the autoscaled concentration of DHEA and 12-HETE, respectively. The mean concentrations of these metabolites were found to have significantly changed among the study groups according to Kruskal-Wallis analysis of variance.

FIGURE 2. Colored heatmap of the pair-wise Spearman's rank correlation coefficients computed for cytokines vs cytokines, cytokines vs eCBs, and cytokines vs oxylipins. The colors refer to the correlation coefficient direction and magnitude, ranging from −1 (blue) to 1 (red). Each box in the heatmap is constructed from the metabolites-cytokines data of the 28 enrolled subjects. The metabolites are ordered according to the corresponding PUFA and the metabolic pathway. The correlation coefficients and the significance \( P \) values corresponding to all computed correlations are provided in the Supplementary Data.
targeted high-performance LC-MS/MS method. In addition, previously published studies were performed on a mix of treated and treatment-naive UC patients,\textsuperscript{29–31} which might be a limitation. Therefore, in this study, only treatment-naive patients were included in the active UC group (Table 1). Moreover, the deep remission patients were selected based on their endoscopy scores and TNF measurement results.

Our findings suggest that inflammation of the colonic mucosa in UC at debut is associated with a significant increase in concentrations of \(\omega-6\) AA–related oxylipins, specifically, PGE\(_2\), TXB\(_2\), trans-LTB\(_{4}\), and 12-HETE, in addition to lower concentrations of \(\omega-3\) eCBs (DHEA and EPEA) (Fig. 1). The \(\omega-6\) AA–related oxylipins are potent immune response regulators. For example, PGE\(_2\), produced via COX within the AA cascade, has a pro-inflammatory effect via IL-6 production and dendritic cell activation and an anti-inflammatory effect via local \(\alpha\)-keto PGF1\(_\alpha\) cell accumulation and lipoxin induction.\textsuperscript{32, 34} Moreover, 12-HETE, produced via 12-LOX within the AA cascade, is a potent chemoattractant for neutrophils.\textsuperscript{35}

In addition, LTB\(_4\) and its isomer trans-LTB\(_4\) stimulate the neutrophil chemotaxis in UC.\textsuperscript{36} Furthermore, TXB\(_2\) is the stable downstream metabolite of thromboxane A\(_2\) (TXA\(_2\)), which is known for causing vasoconstriction, platelet aggregation, and T-cell activation.\textsuperscript{37} Studies on \(\omega-6\) and \(\omega-3\) PUFAs and their bioactive lipid metabolites in IBD patients have revealed an alteration in their mucosal levels.\textsuperscript{5, 32, 38} To our knowledge, our study is the first to report alterations in EPEA and DHA-E levels in colonic mucosa in UC.

Interestingly, our data showed differences in the oxylipin profiles between deep remission patients and healthy controls. The \(\omega-6\)-related oxylipin 15s-HETrE was significantly higher in the UC deep remission group in comparison with the control group, whereas the other investigated lipid metabolites did not differ significantly. Studies suggest that 15s-HETrE has an anti-inflammatory role via suppressing COX-2 overexpression\textsuperscript{39} and inhibiting platelet reactivity and thrombosis.\textsuperscript{40} The UC remission patients enrolled in this study, however, had completely resolved inflammation in the colonic mucosa. Higher levels of 15(s)-HETrE could indicate the importance of this anti-inflammatory oxylipin in maintaining the state of remission. However, due to the low number of patients, this finding was not conclusive, and a further confirmatory study is needed.

We also investigated cytokine gene expression to have an overview of the association between cytokine production at the transcriptomic level and the lipid mediators at the metabolomic level. This allows a deeper interpretation of the variation in the eCB and oxylipin profiles. As our study is purely descriptive, we were more interested in describing the direction and degree of correlation than the statistical significance.

The gene expression of all investigated cytokines was higher in debut patients compared with healthy controls. This finding is in agreement with previous studies.\textsuperscript{34, 41–43} Interestingly, cytokine gene expression was positively correlated with AA-related oxylipins, except for LXA\(_4\) and \(\alpha\)-keto PGF\(_{\alpha}\), where a negative correlation was found (Fig. 2). These 2 oxylipins play an important anti-inflammatory role. For instance, \(\alpha\)-keto PGF\(_{\alpha}\) is a stable metabolite of prostacyclin (PGI\(_2\)),\textsuperscript{44} which inhibits platelet activation and reduces the intensity of the inflammatory response.\textsuperscript{45} LXA\(_4\) is a potent inflammation resolution oxylipin that promotes the clearance of apoptotic cells by macrophages and limits the infiltration of pro-inflammatory leukocytes.\textsuperscript{46} In fact, an LXA\(_4\) analog was found to inhibit TNF and IL-2 mucosal expression in induced colitis in mice.\textsuperscript{47} Accordingly, increasing the levels of LXA\(_4\) and PGI\(_2\) may represent promising targets for intervention. Our data also revealed imbalances in the CYP pathway (Fig. 2), namely between the anti-inflammatory EpETEs and the pro-inflammatory DHETs. This has previously been studied in obesity-induced colonic inflammation\textsuperscript{48} but needs to be further explored in IBD.

In contrast to AA-related oxylipins, the correlation matrix revealed a negative correlation between the cytokine profiles and the eCB profile, in particular regarding EPEA and DHEA. Therefore, our findings suggest a potential role of \(\omega-3\)-derived eCBs in the resolution of inflammation, and we propose novel therapeutic targets. Cannabinoid agonists and endocannabinoid degradation inhibitors in rodent models of IBD have identified a potential therapeutic role for eCBs.\textsuperscript{34, 49} Recently, a potential anti-inflammatory role for EPEA and DHEA was suggested.\textsuperscript{50} This is through the epoxide forms (EEQ-EA and EPEA), which inhibit the production of the pro-inflammatory cytokine IL-6 and promote the anti-inflammatory cytokine

IL-10. However, studies on the effectiveness of ω-3 supplementation in the prevention and treatment of UC have been inconclusive and have failed to establish daily recommended intake. In contrast, a trial study aiming to restore the lipid signaling balance in the intestinal tract by alkaline sphingomyelinase (Alk-SMase) rectal installation found significantly reduced inflammation and TNF expression.

The small sample size in our study precludes subgroup analysis according to the severity of the disease in the UC treatment-naïve group. In addition, the healthy control group was considerably older than the 2 UC groups, which might affect our results. Furthermore, the small size of the UC remission group, which only consisted of males, is considered a weakness in this study. Due to the imbalanced distribution in the analyzed cohort, the effects of both sex and age were not included in our data analysis. Therefore, our findings are exploratory and need to be validated in a larger cohort, in which, preferably, only sex- and age-matched healthy controls are included. This approach might give normally distributed data, and thus allow for the use of parametric statistical tests, which have more statistical power.

CONCLUSIONS

We demonstrated for the first time that the onset of UC is associated with increased levels of ω-6-related oxylipins and decreased levels of ω-3-related eCBs. Furthermore, we have revealed an association between bioactive lipid mediators and pro-and anti-cytokine production. Our findings highlight the mucosal fingerprints of the metabolism of PUFAs, which may be involved in the progression of inflammation and may be considered as potential targets for intervention that need to be explored in more detail in a larger study.

ACKNOWLEDGMENTS

We thank Renate Meyer for administrating the patient samples and Ingrid Christiansen for the technical help performing the TNF levels measurements.
