

Updated checklist of Norwegian Mycetophilidae (Diptera), with 92% DNA barcode reference coverage

JOSTEIN KJÆRANDSEN & GEIR E.E. SØLI

Kjærandsen, J. & Søli, G.E.E. 2020. Updated checklist of Norwegian Mycetophilidae (Diptera) with 92% DNA barcode reference coverage. *Norwegian Journal of Entomology* 67, 201–234.

Up to present 602 species and 65 genera of fungus gnats, family Mycetophilidae, are published from Norway. Extensive collecting supported by the Norwegian Biodiversity Information Centre (NBIC) over the eight last years, with special focus on insect fauna in northern Norway, has documented 240 additional species and 2 additional genera from Norway, of which 118 species are considered as new to science. Based on a thorough review of the species previously published from Norway, we have crossed out six species as misidentified. One new synonym is established: *Boletina conformis* Siebke, 1863 *syn. n.* = *Boletina plana* (Walker, 1856). Two species are restituted based on integrative studies including DNA barcodes. These are *Ectrepesthoneura bucura* Plassmann, 1980 *sp. restit.*, found to be a distinct species separate from *Ectrepesthoneura ovata* Ostroverkhova, 1977, and *Trichonta trifida* Lundstrom, 1909 *sp. restit.*, found to be a distinct species separate from *Trichonta vulcani* (Dziedzicki, 1889). The updated, validated A-checklist includes 821 species of which 703 (86%) refer to formally described species and 118 (14%) to potentially undescribed species, referred to by their interim names as used on BOLD and in our databases. All species are documented with specimens in the museum collections at either Tromsø University Museum (TMU, 781 species, 95%) and/or the Natural History Museum in Oslo (NHMO, 382 species, 47%). Another 14 published species are transferred to a B-checklist with currently unvalidated species, as we fail to recover voucher representatives. Supported by the Norwegian Barcode of Life (NorBOL) network, we have DNA barcoded as many species as possible contributing to the reference library on The Barcode of Life Project (BOLD). Hence, 756 (92%) of the validated Norwegian species are currently documented with DNA barcodes and assigned Barcode Index Numbers (BINs) on BOLD, including the majority of the species considered new to science based on morphology (103 species, 87% of the 118). The checklist, is kept in a short format giving the published species names or interim names as used on BOLD and in our databases, depository information, assigned BINs with indications of discordance, and finally their (2015) Red List status in Norway. An accompanying dataset containing recording details and distribution of all new records from Norway of described species, is published on GBIF and on Norway's Species Map Service (Artskart).

Key words: Diptera, Mycetophilidae, Checklist, Norway, DNA barcode library.

Introduction

Much have happened since Gammelmo & Søli (2006) presented the first complete checklist

of the family Mycetophilidae from Norway 14 years ago. The establishment of the Norwegian Biodiversity Information Centre (NBIC) and the Norwegian and the Swedish Taxonomy Initiatives

(NTI & STI) have paved way for substantial surveys on the insect fauna in the Nordic countries. Furthermore, Norway's and Finland's strong commitments to the International Barcode of Life project (iBOL), through the Norwegian Barcode of Life project (NorBOL) and the Finish Barcode of Life (FinBOL) have contributed to taxonomic upgrades and a better understanding of species and their delimitation, not at least within the family Mycetophilidae.

Johan Heinrich Spalckhawer Siebke was the first in Norway to list 54 species of Mycetophilidae as a part of his ground-breaking and monumental work “*Enumeratio Insectorum Norweticorum*” (Siebke 1877). In the next hundred years or so, only a few species were added through revisionary works of individual genera, i.e. *Allodia Winnertz, 1864* by Hackman (1970), *Phronia Winnertz, 1864* by Hackman (1971), *Trichonta Winnertz, 1864* by Gagné (1981) and *Mycomya Rondani, 1856* by Väisänen (1984). Then, in the 1990s, the interest for fungus gnats expanded considerably, and numerous new species were added to the Norwegian fauna: Kjærandsen (1993) 40 species from cave systems, Søli (1994) 133 species from Jostedalen, West Norway. Then, Bjørn Økland in cooperation with Alexander I. Zaitzev, added 128 more new species (283 in all) after having studied the southern boreal fauna of fungus gnats in South-East Norway over several years (Zaitzev & Økland 1994, Økland 1996, Økland & Zaitzev 1997). Based on these sources and some other minor additions, Gammelmo & Søli (2006) assembled the first checklist containing 470 described species of Mycetophilidae from Norway.

After this first Norwegian checklist, a number of new species have been published: Kjærandsen & Jordal (2007) presented 314 species of Mycetophilidae from Møre og Romsdal county, including 48 species new to Norway, and later added one more species new to science, *P. tuomikoskii* Kjaerandsen, 2009 (Kjærandsen 2009). The next two years, Søli & Kjærandsen (2008) added 50 more new species to Norway, and Søli, Rindal & Hansen (2009) another 15, mostly from SE Norway. Then, in a NBIC project, Søli & Rindal (2012) reported 240 species from Finnmark

county of which 12 were new to Norway. Some new species and records from Norway, have also been added by other authors: *Boletina palmata* Polevoi, 2013 by Polevoi (2013), *Boletina hyperborea* Salmela, 2016 by Salmela et al. (2016), and *Phronia elegantula* Hackman, 1970, *Phronia prolongata* Salmela, in Salmela & Kolsar, 2017 by Salmela & Kolsar (2017). Most recently, the new genus *Coelosynapha* Kjaerandsen, Polevoi & Salmela, 2020 with the species *Coelosynapha loici* Kjaerandsen, Polevoi & Salmela, 2020, was recorded from Reisa National Park (Kjærandsen et al. 2020). In sum, this has raised the number of described species of Mycetophilidae known from Norway from 470 to 602 before this update.

When Kjærandsen & Jordal (2007) reported a surprisingly rich fauna of fungus gnats of the superfamily Sciaroidea from Møre og Romsdal county, they suggested that more thorough investigations in northern Norway would reveal new and different distribution pattern for fungus gnats in Norway than those hitherto recognized. This speculation was based on findings from Sweden where the richest fauna of fungus gnats were documented in the northern parts of the country (see Kjærandsen et al. 2007). Substantial insect collecting surveys throughout northern Norway and on Svalbard, undertaken by the authors during the last decade, and supported by the Norwegian Biodiversity Information Centre through several projects, have indeed confirmed this assumption. The great majority of new species from Norway presented here, thus results from projects in Northern Norway, but a substantial part also from additional projects and collections made available to us from southern Norway (Table 1).

Today, an increasing number of online resources provide early release of species data not published elsewhere. These online records, represents a new type of biodiversity documentation, and have been termed “grey literature” (e.g. Lawrence et al. 2015). Examples of such grey literature include datasets published on GBIF (e.g. Kjærandsen & Jordal 2019), Norway's Species Map Service (Artskart), the Barcode of Life archive, BOLD, and online species facts sheets accompanying national red lists. On the internet, the checklist of fungus gnats of the families Bolitophilidae,

Table 1. Nine major sources for fresh materials of Mycetophilidae from Norway the last eight years.

No. NBIC project name or other sources	Principal investigators	Project grant no.	Period	Study area
1 NBIC: Svalbards tovinger/ Diptera of Svalbard	Geir Søli	70184222/54-11	2012-14	Svalbard
2 NBIC: North-eastern elements of the Norwegian fauna of fungus gnats	Jostein Kjærandsen	70184233/45-14	2015-17	Troms and Finnmark
3 NBIC: Fungus gnats in karst landscapes of Nordland – adding up the fauna of Northern Norway	Jostein Kjærandsen	70184238/27-17	2018-20	Nordland
4 NBIC: Insects from rich fens in Hedmark	Trond Andersen / Linn Katrine Hagenlund	70184235	2016-17	Innlandet (Hedmark)
5 NBIC: Water Mites and Midges in southern Norway (Water M&M)	Elisabeth Stur / Patrycja Dominiaik	70184240/13-18	2019-21	Agder
6 Collecting program of insects in southwestern Norway by Stavanger Museum	Alf Tore Mjøs		2019-22	Agder, Rogaland and Vestland
7 Private insect collecting in southern Rogaland (Sokndal)	Jarl Birkeland		2019-20	Rogaland
8 Private insect collecting in Vestland	Jostein Kjærandsen		2015-20	Vestland
9 Private insect collecting in Nordland	Jostein Lorås		2018-20	Nordland

Diadocidiidae, Ditomyiidae, Keroplatidae and Mycetophilidae at the Vibrant-Scratchpad site “Fungus Gnats Online” (Kjærandsen 2016) constitute another “grey” source. The aim of the present checklist is, thus, to anchor in a single source all species of Mycetophilidae from Norway published in both “white” and “grey” literature. An accompanying dataset with details on records and distribution of all described species is published on GBIF (Kjærandsen 2020), and by way of the The Norwegian Biodiversity Information Centre (Artsdatabanken) made available through Norway’s Species Map Service (Artkart).

Materials and methods

The bulk of the new species presented here results from two projects aimed to study the insect fauna in northern Norway, and supported by the Norwegian Biodiversity Information Centre (NBIC) (see Table 1). A few additional new species resulted from revision of museum collections.

A great number of collecting methods, has been applied to get the best possible coverage of species of fungus gnats in Norway. Malaise traps dominated, followed by window traps. These two

trapping methods yield very different samples depending on the species tendency for heliotaxis and geotaxis, respectively (see Kjærandsen & Jordal 2007). SLAM traps, a smaller version of the Malaise trap, have also been extensively used, although usually resulting in rather low catches of fungus gnats. In open areas like mires and montains, coloured pan traps have proved to be efficient. Light traps may yield good catches of certain species hardly caught by the other trapping methods, but have not been much used by us. Sweep netting, however, has been extensively used and usually give good representation of species in the area, although a few abundant species often dominate the catches. Collecting with use of aspirator in cave systems, both natural and man-made, in wintertime has given good catches of fungus gnats that overwinters as adults (see Kjærandsen 1993). Lastly, larvae have been collected from fruiting bodies of mushrooms or from decomposed wood and reared to adults for identification, or more recently, identified based on DNA barcoding.

After a superficial study, species were sorted out from huge samples stored in alcohol. For the most part, the specimens were chemically dried by use of hexamethyldisilazane (HMDS) (see e.g. Brown 1993), before they were pinned, or glued

to minutiae, and lodged in the entomological collections at either Tromsø University Museum, UiT – The Arctic University of Norway (TMU) or the Natural History Museum in Oslo, University of Oslo (NHMO). Older material are partly stored in 80 % ethanol. For certain species, specimens are kept in ethanol (mostly 95 %) in freezer at TMU as source for further genetic study.

If not readily identified on morphological features, the terminalia were detached, cleared in lactic acid and transferred to glycerine for inspection under light microscope. Afterwards, the terminalia were stored in glycerine in microvials and pinned together with the rest of the specimen. In specimens to be DNA barcoded, one leg, usually the fore leg with coxa, was detached, stored in 96 % ethanol and through NorBOL sent to the Canadian Centre for DNA barcoding, BIO (Guelph, Ontario, Canada), for DNA extraction and bi-directional Sanger sequencing.

The final step in the identification process, consists of carefully analyzing ID-trees resulting from the DNA barcoding and re-examine all cases where a mismatch appeared between our morphological determination and the automated BIN assignments. This stage may likely include additional preparation for further morphological studies.

Results

Magnitude and distribution of the examined species records

The present checklist is based on 22.608 georeferenced and vouchered species records from all over Norway (Figure 1). They represent 835 species in 67 genera. Altogether, we regard the studied areas to be quite representative for the major bioclimatic zones of Norway, leaving only the alpine zone largely uncovered. When the records are broken down to 11 administrative counties, however, some more uneven efforts and species distributions emerge. Northern Norway is almost equally explored (45% of the total species records) as is Southern Norway, but has definitely the highest number of recorded species with 622

species (74%) in Troms and Finnmark and 529 species (63%) in Nordland. Northern Norway also by far, has the highest number of species assumed to be new to science, 80 in Troms and Finnmark and 47 in Nordland. Trøndelag and the southernmost parts of Norway, on the other hand, represent the least well-studied areas, with Agder and Rogaland having the lowest number of both records and species. The rest of western Norway, Innlandet and Viken (including Oslo) is fairly well and evenly researched, and among them only Innlandet shows potential for a high number of new species to science. Finally, from the arctic offshore islands Svalbard, Bjørnøya and Jan Mayen only 14 species have been registered, yet 4 of the species from Svalbard are considered new to science.

DNA barcoding

In all 4897 samples of Mycetophilidae from Norway (including 360 public records not submitted by us), have been submitted to DNA barcoding on BOLD. Of these samples, 4414 or 90 % have resulted in sequences assigned to 772 different BINs, i.e. clusters that are likely to represent different species. Since we have submitted material, and have access to sequences from other Nordic countries, in all 813 different BINs are assigned to 756 of the species recorded from Norway. Of the 756 species with assigned BINs, 650 (86 %) have a perfect match between our identification based on morphology and a single BIN. Another 68 (9 %) of the species have multiple BINs, of which 57 species share two BINs each, 9 species share 3 BINs each, one species shares 5 BINs, and one species shares 7 different BINs. Finally, 39 (5 %) of the species have BINs shared with other species from Norway: 16 BINs are shared between two species, one BIN is shared among three species, and one BIN is shared among four species.

Species assumed to be new to science

No less than 118 species belonging to 23 different genera of Mycetophilidae recorded from Norway are currently recognized as potential new species

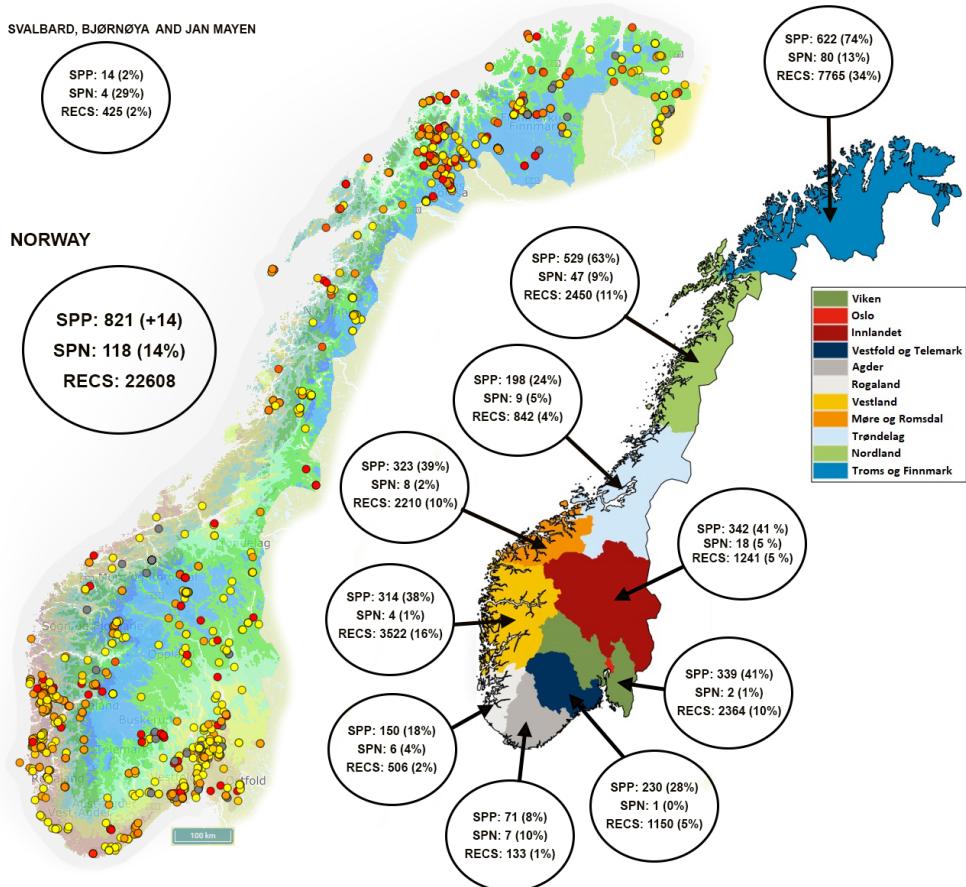

FIGURE 1. The map to the left displays bioclimatic zones and, by coloured dots, geo-coordinates representing 22.608 records of Mycetophilidae in Norway. (Since records of the 14 unvalidated species are published on Norway's Species Map Service, they are included in the statistics here.) Yellow dots denote the highest coordinate precision while red denote the lowest precision. A high precision, in general refers to more recent records. The five major bioclimatic zones are boreonemoral (pale red), southern boreal (yellow), middle boreal (pale green), northern boreal (dark green) and alpine (blue). On the map to the right, the 22.608 species records are apportioned on the administrative counties in Norway (Oslo and Viken are merged). Abbreviations: **SPP** = number of species recorded and its proportion of the 835 species; **SPN** = number of species assumed to be new to science and its proportion of the total number of species recorded in that county; **RECS** = total number of species records for a given county and its proportion of all the 22.608 records (Bioclimatic zones and geo-coordinates from Norway's Species Map Service).

to science. Numerous of these new species, have been recognized for some time among fungus gnat researchers, predominantly on morphological characters or DNA-barcoding results. Some of them may eventually, turn out to represent species already described from North America or misinterpretations of European species. If so, DNA barcodes will be of paramount importance to trace back a link between their interim name presented

here and their actual name. Noteworthy, we do not consider a species as new, based on DNA barcodes and their BIN assignments alone. Had we done so, using the BIN system as proxies for species, another 85 potential new species, could be added to the checklist. Consequently, designation of new species must involve thorough examinations of both morphological and molecular characters. It is further important to state that the process of

selecting species that we aim to describe as new to science is dynamic, and by no means conclusive nor completed at this stage. For some difficult species groups we currently have still not carried out the necessary comparative studies to decide on their status. For others we have concluded that the BIN segregation appears to be misleading and will argue to merge two or several BINs into one operative species. In the end, we anticipate to end up somewhere between 100 and 150 species new to science.

Synonyms revived as good species

Two species are restituted based on integrative studies including DNA barcodes and their BINs:

The two species *Ectrepesthoneura bucura* Plassmann, 1980 sp. restit., and *Ectrepesthoneura ovata* Ostroverkhova, 1977 were originally synonymized by Kjærandsen et al. (2007). DNA barcoding results, however, justify to treat them as distinct species, although the morphological differences are small (Figure 2). *E. ovata* in BIN BOLD:ACY1765 is characterized by (1)

wider and more sessile apical split of tegite 9, (2) blunt apicolateral corner of tegite 9, and (3) subtriangular ventromedial projections of the gonocoxite, whereas its “twin”, *E. bucura* in BIN BOLD:ADY3228, has (1) narrower and more projected apical split of tegite 9, (2) sharp apicolateral corner of tegite 9, and (3) subquadrangular ventromedial projections of the gonocoxite. The mean distance between the two BINs is 2.41% (p-distance).

Within *Trichonta* Winnertz, 1864 DNA-barcoding has revealed a challenging complex of species near *Trichonta vulcani* (Dziedzicki, 1889). The Norwegian sequences of these species are clearly segregated into four clusters (Figure 3). As far as we know, four species are involved: *T. vulcani* (BIN BOLD:ADL1998), *Trichonta JKJ-spF* (BIN BOLD:ACI8376), *T. trifida* Lundstrom, 1909 (BIN BOLD:ADO7293), and *T. tristis* (Strobl, 1898) (BIN BOLD:ADY2587). The terminalia of the four species differs in several details, but in particular, the outline of the sclerotized, ventromedial margin of the gonocoxite segregates them in accordance with

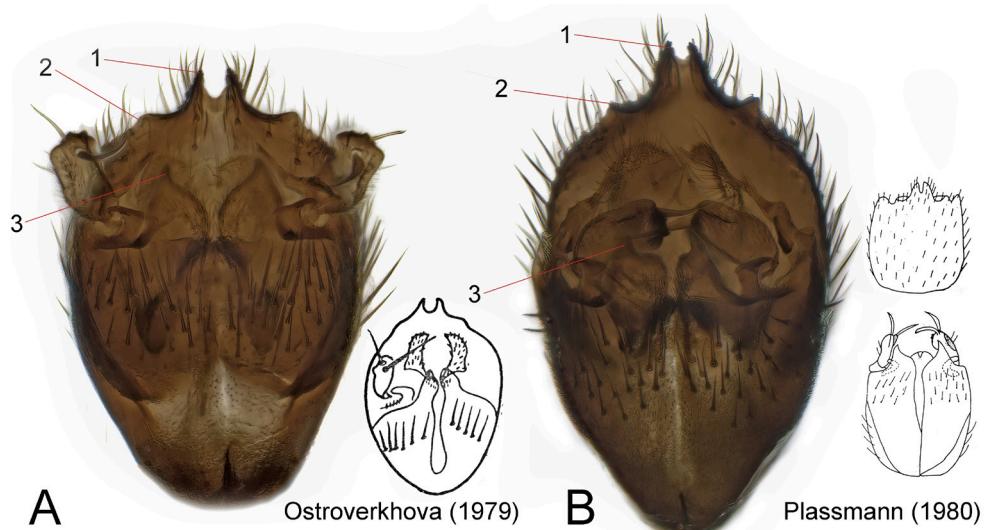

FIGURE 2. The two species (A) *Ectrepesthoneura ovata* Ostroverkhova, 1977 (BIN BOLD:ACY1765) and (B) *Ectrepesthoneura bucura* Plassmann, 1980 sp. restit. (BIN BOLD:ADY3228) were originally synonymized. Results achieved by DNA barcoding, however, justify to treat them as distinct species, although the morphological differences are small. Red arrows points at critical characters for their identification: 1 = apical split of tegite 9, 2 = apicolateral corner of tegite 9 and 3 = ventromedial projections of the gonocoxite. Copies of original drawings from the literature is depicted to the right of the photos.

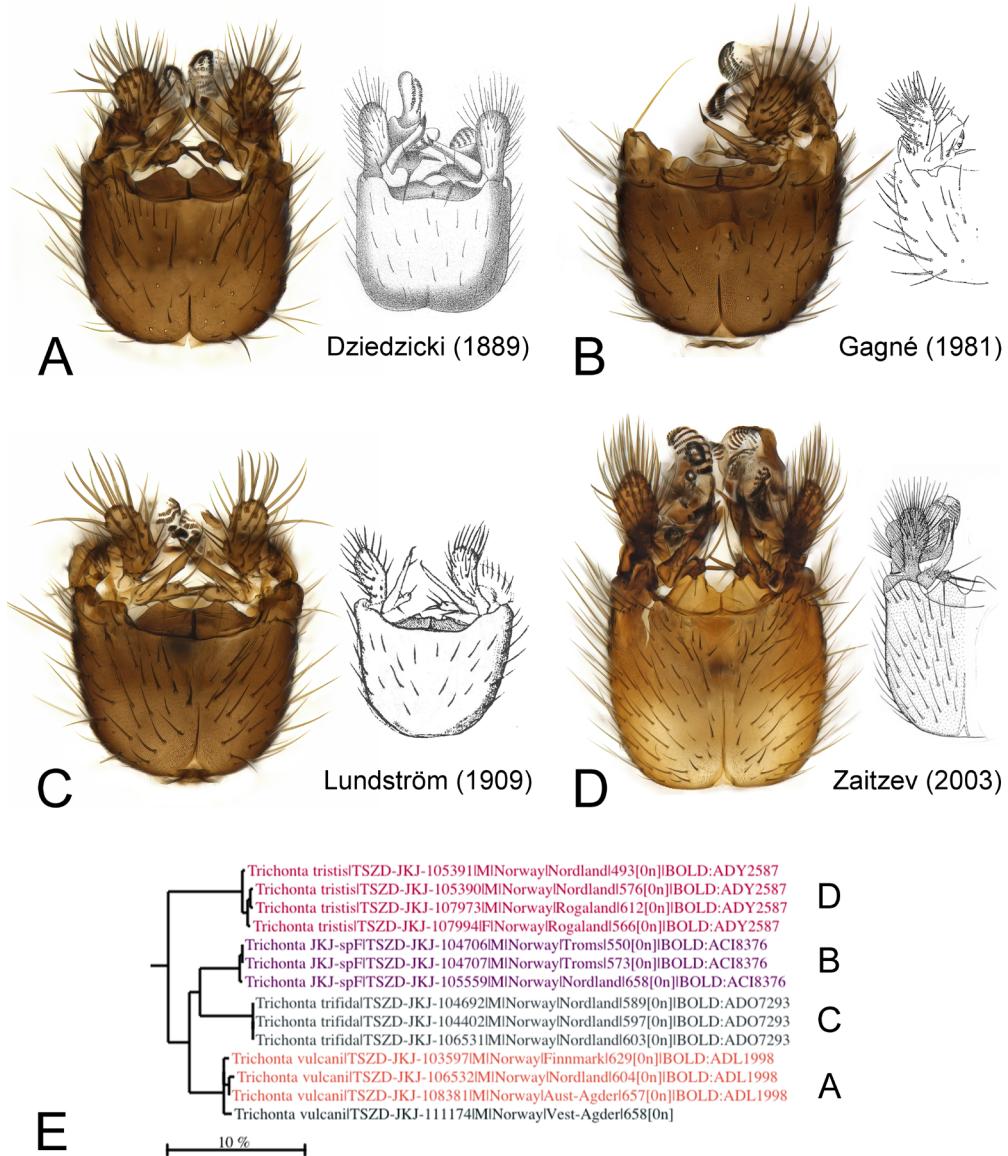

FIGURE 3. Norwegian species of the *Trichonta vulcani* species complex. **A** = *Trichonta vulcani* (Dziedzicki, 1889), BIN BOLD:ADL1998 (specimen TSZD-JKJ-106532). **B** = *Trichonta JKJ-spF* (with left gonostylus detached), BIN BOLD:ACI8376 (specimen TSZD-JKJ-105559). **C** = *Trichonta trifida* Lundstrom, 1909 sp. restit., BIN BOLD:ADO7293 (specimen TSZD-JKJ-106531). **D** = *Trichonta tristis* (Strobl, 1898), BIN BOLD:ADY2587 (specimen TSZD-JKJ-105391). **E** = Subsection of ID-tree (Kimura-2-distance) obtained from BOLD with Norwegian sequences and BIN assignments of the four species. Letters to the right of the ID-tree corresponds to the images. Copies of available drawings in the literature, corresponding to the four species, are depicted to the right of the photos.

the BINs (apparently also in accordance with published illustrations). Based on these results *T. trifida* Lundstrom, 1909 sp. restit. must be treated as a distinct species separate from *T. vulcani*.

A new synonym

Boletina plana (Walker, 1856)

= *Boletina conformis* Siebke, 1863: 84 NEW SYNONYM

Sources: Siebke (1863, 1877), (Hackman et al. 1988), Chandler (2005), Gammelmo & Søli (2006)

Remarks: We have studied the type material of *B. conformis* (Figure 4) deposited at NHMO, and found that it is identical to *B. plana*. The species, was described from Dovre in Norway (Siebke, 1863). The holotype, was studied and illustrated by Matile (1983) who did not realize its synonymy with *B. plana*.

Published species removed due to positive misidentifications

Docosia moravica Landrock, 1916

Sources: Søli & Rindal (2012)

Remarks: The material for the original record published in Søli & Rindal (2012) has been re-examined and found to be a misidentification of *Docosia mulleri* Plassmann, 1987. Zaitzev (1994) erroneously illustrated *Docosia mulleri* as *Docosia moravica*.

Mycetophila czizeki Landrock, 1911

Sources: Søli (1994), Chandler (2005), Gammelmo & Søli (2006)

Remarks: The material for the original record published in Søli (1994) has been re-examined and found to be a misidentification of *Mycetophila formosa* Lundström, 1911.

Mycetophila mitis (Johannsen, 1912)

Sources: Gammelmo & Søli (2006), Søli & Rindal (2012)

FIGURE 4. Examination of the holotype of *Boletina conformis* Siebke, 1863 syn. n., deposited at Natural History Museum in Oslo (NHMO), revealed that the species is a junior synonym of *Boletina plana* (Walker, 1856). The terminalia was probably detached and mounted by L. Matile, who studied and illustrated the holotype in the early 1980-ies (Matile 1983).

Remarks: The material for the original record published in Søli & Rindal (2012) has been re-examined and found to be a misidentification of a species in the yet unresolved *Mycetophila stolida* species complex.

***Mycetophila sigillata* Dziedzicki, 1884**

Sources: Søli, Rindal & Hansen (2009)

Remarks: The material for the original record published in Søli, Rindal & Hansen (2009) has been re-examined and, following Zaitzev (2003), found to belong to *Mycetophila subsigillata* Zaitzev, 1999. In fact, Dziedzicki (1884) described two varieties of *Mycetophila sigillata* of which one was segregated as a separate species by Zaitzev (1999). All checked records of *Mycetophila sigillata* from Norway, Sweden and Finland studied so far, show to refer to *Mycetophila subsigillata*.

***Brevicornu setigerum* Zaitzev, 1995**

Sources: Søli & Rindal (2012)

Remarks: The material for the original record published in Søli & Rindal (2012) has been re-examined and found to be a misidentification of *Brevicornu radiatum* Lundström, 1911.

***Sceptonia pilosa* Bukowski, 1934**

Sources: Søli, Rindal & Hansen (2009)

Remarks: The material for the original record published in Søli, Rindal & Hansen (2009), has been re-examined and found to be a misidentification of the yet unresolved *Sceptonia fumipes* species complex, consisting of 7 different BINs.

The revised checklist

The main A-checklist includes species representing accepted names, and species considered as new to science, limited to those represented by validated vouchers in museum collections. Species published without validated vouchers are listed at the end, in a separate B-checklist.

A-checklist, 820 species with validated records in the museum collections of TMU and/or NHMO, and one additional species deposited at Regional Museum of Lapland, Finland (LMM)

In the main list, genera are listed in alphabetic order, as are species within each genus. Species claimed to be new to science are found at the end within each genus, using their interim-name code species epithet as used on BOLD and in our databases.

Below each species name are listed key facts about its status, given in three sections, each divided by a vertical bar (|):

The first section denotes the depository of voucher specimens with the following three codes: **TMU** = Tromsø University Museum in Tromsø (new administrative name is The Arctic University Museum of Norway, UiT – The Arctic University of Norway). **NHMO** = Natural History Museum in Oslo, University of Oslo. **LMM** = Regional Museum of Lapland, Rovaniemi, Finland (concerning one species only).

The middle section lists all Barcode Index Numbers (BINs) associated by us with the species name, followed in brackets by the match ratio (integers) between our morphological identification and the automated BIN-assignments. In the few cases where the BIN originates from other sources, e.g. GenBank, this is commented on. A ratio of 1:1 points to a perfect match between our identification based on morphology and a single BIN. A ratio of 1:*n*, where *n* varies between 2 and 7, indicates that our morphologically identified vouchers are represented by 2 to 7 BINs. A ratio of *n*:1, where *n* varies between 2 and 4, indicates that 2-4 morphologically separated and identified species appear merged into a single BIN. In the latter cases, the shared species names are listed for comparison. In the list, a horizontal bar (–) denotes that the species is not yet barcoded due to lack of available fresh material; "FAILED" denotes that all submitted specimens failed to give any barcode compliant sequences (imperfect sequences may still exist); "PENDING" denotes submitted specimens still awaiting BIN-assignment on BOLD.

The last section quotes the most recent

Norwegian Red List status (Gammelmo et al. 2015), with the code "NEW" indicating species not previously recorded from Norway and, hence, not yet evaluated for the Red List.

The B-checklist, 14 published species without validated vouchers

Here we list sources for, and briefly comment on 14 additional species published from Norway for which we have not been able to trace back and verify any voucher material. We assume that the majority, is correctly reported from Norway, but we refrain to include them in the A-checklist until vouchers have been located and validated, or new records are found, determined and deposited in museum collections. Most species listed here concern records published by Økland (1996) and Økland & Zaitzev (1997). The original voucher material for these important and pioneering studies, has long been searched for in vain and must be regarded as lost.

Boletina cornuta Zaitzev, 1994

Sources: Økland (1996), Økland & Zaitzev (1997), Chandler (2005), Gammelmo & Søli (2006)

Remarks: The original voucher material for the records published by Økland (1996) and Økland & Zaitzev (1997), is regarded as lost. The species, is scarcely recorded in both Sweden and Finland, so it is likely that it occurs in Norway. Its inclusion in the A-list pending validated records.

Dynatosoma rufescens (Zetterstedt, 1838)

Sources: Siebke (1877), Hackman et al. (1988), Økland (1996), Økland & Zaitzev (1997), Chandler (2005), Gammelmo & Søli (2006)

Remarks: We are unable to trace any voucher specimens for the Norwegian record given by Siebke (1877) and repeated in Catalogue of

Palaearctic Diptera (Hackman et al. 1988). The original voucher material for the records published by Økland (1996) and Økland & Zaitzev (1997), are also regarded as lost. The species is not common, but widely recorded in both Sweden and Finland, so it is likely that it occurs in Norway. Its inclusion in the A-list pending validated records.

Exechia nigrofusca Lundstrom, 1909

Sources: Chandler (2005), Gammelmo & Søli (2006)

Remarks: We are unable to trace any voucher specimens for the country record given by Chandler (2005), repeated in Gammelmo & Søli (2006). The species is rare, but recorded in both Sweden and Finland, so it is likely that it occurs in Norway. Its inclusion in the A-list pending validated records.

Leia bimaculata (Meigen, 1804)

Sources: Hackman et al. (1988), Økland & Zaitzev (1997), Gammelmo & Søli (2006)

Remarks: We are unable to trace any voucher specimens for the country record given in Catalogue of Palaearctic Diptera (Hackman et al. 1988). The original voucher material for the records published by Økland & Zaitzev (1997), is also regarded as lost. The species is widely recorded in both Sweden and Finland, so it is likely that it occurs in Norway too. Its inclusion in the A-list pending validated records.

Leia crucigera Zetterstedt, 1838

Sources: Hackman et al. (1988), Chandler (2005), Gammelmo & Søli (2006)

Remarks: We are unable to trace any voucher specimens for the country record given in Catalogue of Palaearctic Diptera (Hackman et al. 1988), repeated in Chandler (2005) and Gammelmo & Søli (2006). The species is sparcely recorded in both Sweden and Finland, so it is likely that it occurs in Norway too. Its inclusion in the A-list pending validated records.

Mycetophila immaculata Dziedzicki, 1884

Sources: Økland (1996), Økland & Zaitzev (1997), Chandler (2005), Gammelmo & Søli (2006)

Remarks: The original voucher material for the records published by Økland (1996) and Økland & Zaitzev (1997), is regarded as lost. The species, is scarcely recorded in both Sweden and Finland, so it is likely that it occurs in Norway too. Its inclusion in the A-list pending validated records.

***Mycetophila lapponica* Lundstrom, 1906**

Sources: Økland (1996), Økland & Zaitzev (1997), Chandler (2005), Gammelmo & Søli (2006), Søli & Rindal (2012)

Remarks: The original voucher material for the records published by Økland (1996) and Økland & Zaitzev (1997), is regarded as lost. The material for the record published in Søli & Rindal (2012) has been re-examined and found to be a misidentification of *Mycetophila* GS-spA and *Mycetophila uliginosa* Chandler, 1988. The species, was described from northern Finland and is scarcely recorded in both Sweden and Finland, so it is likely that it also occurs in Norway. Its inclusion in the A-list pending validated records.

***Mycomya (Mycomya) mituda* Vaisanen, 1980**

Sources: Økland (1996), Økland & Zaitzev (1997), Chandler (2005), Gammelmo & Søli (2006)

Remarks: The original voucher material for the records published by Økland (1996) and Økland & Zaitzev (1997), is regarded as lost. The species described from Finland, is scarcely recorded in both Sweden and Finland, and is a likely species to occurs in Norway. Its inclusion in the A-list pending validated records.

***Mycomya (Mycomya) norna* Vaisanen, 1984**

Sources: Økland (1996), Økland & Zaitzev (1997), Chandler (2005), Gammelmo & Søli (2006)

Remarks: The original voucher material for the records published by Økland (1996) and Økland & Zaitzev (1997), is regarded as lost. The species, was described from and is scarcely recorded in Finland, so it is likely that it also occurs in Norway. Its inclusion in the A-list pending validated records.

***Mycomya (Mycomyopsis) penicillata* (Dziedzicki, 1885)**

Sources: Økland (1996), Økland & Zaitzev (1997), Chandler (2005), Gammelmo & Søli (2006)

Remarks: The original voucher material for the records published by Økland (1996) and Økland & Zaitzev (1997), is regarded as lost. The species is widely recorded in both Sweden and Finland, so it is likely that it occurs in Norway too. Its inclusion in the A-list pending validated records.

***Sceptonia tenuis* Edwards, 1925**

Sources: Økland (1996), Økland & Zaitzev (1997), Chandler (2005), Gammelmo & Søli (2006)

Remarks: The original voucher material for the records published by Økland (1996) and Økland & Zaitzev (1997), is regarded as lost. The species is widely recorded in both Sweden and Finland, so it is likely that it occurs in Norway too. Its inclusion in the A-list pending validated records.

***Sciophila distincta* Garrett, 1925**

Sources: Økland & Zaitzev (1997), Chandler (2005), Gammelmo & Søli (2006)

Remarks: The original voucher material published in Økland & Zaitzev (1997), is regarded as lost. This species, was originally described from North America, and the Norwegian records are the only one from the Palaearctic Region. The fact that this species, to the best of our knowledge, has never been illustrated may explain why it is not recorded elsewhere from Europe. A.I. Zaitzev in his Holarctic revision of the genus *Sciophila* Meigen, 1818 (Zaitzev 1982) apparently did not study the type material, deposited at British Museum of Natural History, and thus did not illustrated the species. Examination of the type material is crucial to clarify if it may hide among the assumed new species recorded from Norway.

***Sciophila exserta* Zaitzev, 1982**

Sources: Økland (1996), Økland & Zaitzev (1997), Chandler (2005), Gammelmo & Søli (2006)

Remarks: The original voucher material for the records published by Økland (1996) and Økland & Zaitzev (1997), is regarded as lost. This species, was originally described from North America and the Norwegian records are the only one from the Palaearctic Region. The fact that A.I. Zaitzev described and illustrated this species makes it highly likely that his determination of the Norwegian record was correct. The species belongs to a difficult species group, and may be confused with other species in Europe.

***Trichonta comis* Gagne, 1981**

Sources: Søli (1994), Økland & Zaitzev (1997), Chandler (2005), Gammelmo & Søli (2006)

Remarks: The original voucher material published by Søli (1994) and Økland & Zaitzev (1997), is regarded as lost. The rarely recorded species, was described from Finland, so it is likely that it occurs in Norway too. Its inclusion in the A-list pending validated records.

Unconfirmed, grey-published species on Norway's Species Map Service (Artkart)

Despite contacting the contributor, we have not received any confirmation, nor information on the depository of reference material for the following species.

Discussion

The revised checklist of Norwegian Mycetophilidae lists 821 species, all with confirmed vouchers, and another 14 species previously published but without vouchers. Excluding assumed undescribed species, 703 vouchered species remains. This is about the same species diversity of Mycetophilidae as reported from Finland (Jakovlev 2014), with additions by Salmela & Kaunisto (2015), Salmela et al. (2016),

Salmela & Kolsar (2017) and Kjærandsen et al. (2020). It is slightly more than is known from Sweden (Kjærandsen 2016). Yet, Finland shares only some 87 %, and Sweden some 92 % of its species with Norway. Including the 118 assumed undescribed species, Norway has by far the highest diversity of Mycetophilidae reported to date in any Nordic country. Still, more species will undoubtedly emerge in the future, but looking at the country as a whole, we assume the present set of records depict a mean, representing the major regions and different landscapes in a fair way (Fig. 1). Still, mountainous areas above the treeline remains poorly covered in Norway, and among the counties, Agder, Rogaland and Trøndelag remain among the least studied.

For the majority of species included in the checklist (92 %), we present a link between a species' name based on morphological identification and its barcodes and assigned BINs. Such a high degree of barcode coverage linked to morphologically identified materials has never before, been presented for the family Mycetophilidae, and probably not for any other family of Diptera in Norway. It is our expectation that this objective reference to BINs, will increase the reproducibility of this study tremendously, as it will enable examination and verification of our determinations by others through the BOLD archive. This will meet the demand for a higher degree of replicability in entomological biodiversity surveys as pointed out by e.g. Owens (2018) and Monckton et al. (2020). The same could in theory, be achieved by re-checking the thousands of vouchers deposited in our museum collections, but the BIN system clearly makes this process much more efficient as taxonomists all over the world now can check our determinations against their own material.

Given the fragmented and often low quality descriptions and illustrations available in the literature, it is likely that our list still covers some errors. Regular contact with other experts in the field, however, allow us to discuss our interpretations of troublesome species and thus eliminate the chances for misidentifications. For numerous species, we have checked type materials and learned how to properly identify

them. Nevertheless, with a diversity as displayed by Mycetophilidae, our determinations, are still based largely on original or subsequently published illustrations of the species terminalia. Hence, the barcodes and assigned BINs on BOLD have truly been a great support in our identification of species. The sequence data allows us to sort out difficult species complexes and straighten misunderstandings about species identities, as well as correcting the inevitable, and frankly, not insignificant, self-error rate. The process of building the reference library on BOLD has been gradual and iterative over the last decade, and literally thousands of hours have been spent “post-sequence” to go through the BINs and recheck specimens morphologically in order to correct errors and where appropriate emend the definition of the species. In the process numerous previously overlooked species were uncovered.

The *Trichonta vulcani* species group (Figure 3) makes a good case to illustrate how the species interpretations have changed and narrowed over time. Gagné (1981), in his Holarctic monograph of *Trichonta*, failed to include *Trichonta tristis* (described as *Phronia* and not illustrated in the original publication) and regarded *Trichonta trifida* a junior synonym of *Trichonta vulcani*, although he did not check any type material. As *Trichonta vulcani*, Gagné (1981) probably illustrated what we now believe is a species unknown to science, *Trichonta JKJ-spF*, which by BIN association has shown to be widely distributed in North-America as well as in Norway. Zaitzev (2003) recognized and illustrated *Trichonta tristis* as a separate species, but retained *Trichonta trifida* as a junior synonym of *Trichonta vulcani*. Our DNA barcoding clearly separates between four different BINs from Norway, corresponding to these four rather similar yet morphologically distinct species. We consider, however, it naive to believe that the machine generated BIN assignments on BOLD perfectly reflects the true speciation events among fungus gnats. There are 39 apparent conflicts where two to four morphologically distinct and separated species merge into the same BIN. In these cases, we retain the species as is, pending future studies involving other gene regions to prove the unlikely scenario that they actually

belong to polymorphic species. A much larger proportion concerns cases where a morphologically identified species split into two or more BINs. For the majorities of such cases, we have re-examined the specimens looking for morphological evidence that they actually are different species. Usually, then, the BINs reflects closely related species pairs, with one or more unnamed species in addition to the described one. In a few cases, old synonyms have been revived in this process. Still, for 85 cases of BIN splits, we currently retain the species as one name with two or several different BINs, pending further studies.

By experts it has long been realized that the Nordic fauna of Mycetophilidae holds a substantial proportion of undescribed species, and that the finding of new such undescribed species greatly surpass the formal description of new species. In the Swedish checklist of fungus gnats (Kjærandsen et al. 2007), 34 species were assumed to be new to science, of which the majority still today remains undescribed. (These species are also included as undescribed in the present list). In the grey-literature, specifically the BOLD database, these undescribed species have appeared under their informal name for many years. This happens inevitably as the species are both associated with unique barcodes and BINs, and can hardly be ignored. Without a large scale, focused effort to describe them, the list of species assumed to be new to science should continue to grow, although for the now rather well studied Norwegian fauna of Mycetophilidae perhaps at a declining rate.

Acknowledgements. Insect collecting surveys throughout northern Norway were financially supported by Tromsø University Museum, UiT – The Arctic University of Norway (TMU), UiO, The Natural History Museum of Oslo (NHMO) and The Norwegian Biodiversity Information Centre (NBIC). At TMU we are very grateful to Martin T. Dahl and Patrycja Dominiak (technicians) and to Jon Peder Lindemann (PhD student) who assisted in the fieldwork, the DNA-barcoding and dry-mounting of the pinned specimens, and to Amandine Deschamps who recorded the plant species community at the collecting sites, fulfilling the Nature in Norway (NiN) registration requirements of the NBIC projects. At NHMO we are in particular, grateful to Trude Magnussen (former PhD student) who participated in the field work, sorted through material from several locations, and allowed us to use results

from her exhaustive and exciting study of the world fauna of *Allodia*. Jukka Salmela (Regional Museum of Lapland, Rovaniemi) has kindly shared with us sequences of fungus gnats submitted from Finland through FinBOL, used to build the reference library, and also material of one species new to Norway. A number of other people have provided us with invaluable contributions to our collections. This consider from the University Museum of Bergen Linn Katrine Hagenlund, Gunnar M. Kvifte, Steffen Roth and Trond Andersen; at NTNU's University Museum Elisabeth Stur, Torbjørn Ekrem and Patrycja Dominik contributed; and at University of Stavanger (UiS), Stavanger Museum Alf Tore Mjøs made substantial contributions from southwestern Norway. Donations from private collecting were kindly offered by Jarl Birkeland (Rogaland, Sokndal), Jostein Lorås (Nordland) and Jon Peder Lindemann (Viken og Oslo). We are very grateful to each one of you, further details on the major contributions are provided in Table 1.
